Now that the season is about over for producing, how to keep it is next in order. Sulphur fumes have been relied on, but it does not destroy the egg of the moth; besides, it renders the honey unsalable for several days on account of the disagreeable odor. But to look the honey over every week, waiting for cold weather to kill the moth, is a tedious job, if you have a ton or two. Please tell us the latest new idea on the subject. Is tiering up and leaving it on the hive till October a good plan? or will the bees uncap and carry it down stairs to feed the kids? W. H. RITTER.

North Springfield, Mo., Aug. 1, 1886.

The latest idea on the subject, friend R., is, so far as I know, keeping Italian bees. With these we have not seen a moth-worm in our honey for the last two or three years. You may remember that Doolittle gives a similar experience. I certainly would not go to the trouble of fumigating comb honey until I saw traces of the moth-worm in the comb. Where comb honey contains pollen I believe there is a much greater tendency to moth-worms. I would not leave honey on the hives at all until October, because it is certain to darken it so as to injure the sale of it more or less.

EXCHANGING COLONIES TO STOP ROBBING, AS RECOMMENDED IN THE A B C OF BEE CULTURE.

In 1885 I had a swarm come off on the 4th of July. It was a small one, but I fed it and brought it through the winter; and after I got the A B C I determined to do away with all my old hives, or boxes, and use only Simplicity and chaff, after your pattern. I transferred about the first of May into my hives. Well, I found that my July swarm had lost its queen, and the other bees were robbing it in the bargain. I ordered an albino queen; and on May 11th, after trying every thing else, I could not get ahead of the robbers; so I tried dealing on the rogue plan. I moved the colony, that was doing the most robbing, from its stand, and placed the July swarm in its place; and I found that it was not long until I had a good working colony, and they filled the first story of the Simplicity; and on the 11th of this month they threw out a very large swarm. I then examined the albinos, and found that they had 5 queen-cells on hand. Now, what I want to know is, How am I to deal with those 5 cells? as I shall like to save the queens if I can, and introduce them into some black colonies that I have; and I know that, if left to themselves, they will be destroyed, or possibly swarm out, as it is too late for that kind of business. I think that, by feeding the swarm that came off on the 11th, I may be able to carry it over the winter; they are doing good work. I put them on fdn., and they are drawing it out very fast, and gathering very fast.

I am clerking in a store in this place; and at night, after working-hours, I have made 5 chaff hives and 4 Simplicities; and this winter I expect to make more of the chaff for next season.

A. L. LANE.

Duncannon, Perry Co., Pa., Aug. 18, 1886.

Friend L., there is no way you can utilize queen-cells unless you have queenless colonies to receive them. A lamp nursery would receive them, it is true; but you would be in just as much need of queens to receive the hatched queens as you were before. It does not need, however, a whole colony of bees to take care of a queen-cell until the queen begins to lay, and herein is the saving of utilizing nuclei. One of your black colonies should have been divided into two or more parts a few days before queen-cells were ready to be removed.

BEES VERSUS FRUIT.

Mr. A. Cameron, on page 619, has suggested a grand idea. In his defence of bees, No. 2, it should say, "Without bees or *other insects*, many kinds of bloom would not bear," etc.

In No. 3, he says they do suck the juice from *all* broken fruit. The word *all* should not be used, as there are many kinds of fruits they do not work on.

There is some ignoramous prejudice working up against me, that my bees work on apple-bloom so that our trees do not bear enough apples. Nevertheless I have nearly 60 acres of standard orchard, and a general nursery stock for sale, besides the orchard. How inconsistant, that I would go to the expense of raising a large apple-orchard, then keep a lot of bees to hinder it from producing me an income! Send me a sample of Mr. Cameron's hints, as soon as printed. E. LISTON.

Virgil City, Cedar Co., Mo., Aug. 5, 1886.

FEEDING MILK DURING A DROUGHT; HOW BEES LIKE IT.

You wish to know if any one has tried feeding milk during a drought. Yes; and I will give you my method of doing so. I take new milk, direct from the cows, boil it a little, which makes the clot rise to the top. I skim this off and add a teacupful of sugar to a quart of milk; but sometimes I do not put in any sugar at all, and the bees seem to take it "straight," just as well after once getting started. Boiling prevents souring, and coagulates the excess of fatty matters, which are indigestible, and are best removed.

HOW TO FEED.

I made some boards, as described in the A B C, for giving water to bees, and inverted glass fruit-jars of milk on them. Is it a success? Yes. I have a lot of young Yorkshire pigs, and it is hard to tell which acts most like a hog, the bees or the pigs.

The drought continues, and for severity it has not been equaled for 35 years, says the "oldest inhabitant." During the early spring, honey was abundant; but making swarms and nuclei it was speedily used up, and I have been feeding since July 1st, and I have not taken a pound of honey this season. The honey-dew never failed us before in a dry season; but this year it is a total failure with every thing. H. W. PALLIES.

Mehama, Marion Co., Oregon, Aug 10, 1886.

BEES GOING DOWN A STOVE-PIPE FROM WHICH SMOKE WAS ISSUING.

A few days ago I was baking a pie which I had sweetened with honey. Our oven was defective, so that a draft went directly through it. In a little time I saw bees coming down the pipe and escaping half dead, through a little opening on top of the oven. I went out and found that a lot of bees were darting into the smoke, while now and then one found its way into the pipe. That pie was expensive, as I think 200 bees perished before it was baked. As soon as I took the pie out of the oven the bees ceased "fighting with the pipe," Perhaps you would do well to ask some of your readers if the above is not the real secret of bees fighting with stove-pipes. MRS. JAS. FENNELL.

Shelburne, Ont , Canada, Aug. 18, 1886.

HONEY TO BE NAMED.

I send you this day a small bottle of something my bees have been gathering, principally through July. I think it will kill the bees next winter. Is it honey-dew? 47—E. B. SMITH, 70.

New Milford, Susq. Co., Pa., Aug. 30, 1886.

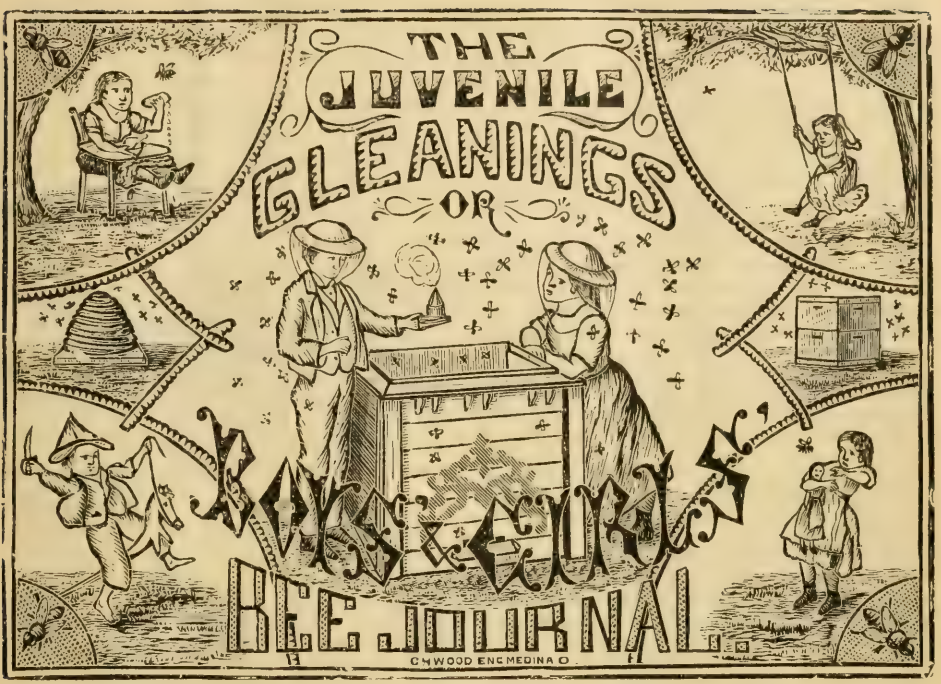
Friend S., I do not think the sample you send is honey-dew, nor do I think it will kill the bees. The color is pretty fair, and the flavor comes, it seems to me, the nearest to the wild sunflower, growing in swamps, of any thing I know of. Have you not a swamp, within a radius of a mile or so of your apiary, that was covered with yellow blossoms when the bees were gathering this honey?

IS HONEY-DEW THE CAUSE OF THE NAMELESS BEE-DISEASE?

In GLEANINGS, August 15, page 644, H. D. Mason mentions that new bee-disease. I think it is certainly caused by honey-dew. By removing combs containing said honey, I can see no trace of it. I have one frame of honey I think would start it in any colony that it was given to. You can have it to experiment with, if you wish. SAMUEL HEATH.

Rimer, Pa., August 24, 1886.

No doubt, friend H., the honey you have affects the bees so as to make them resemble those having the nameless bee-disease; but as we have seen it so many times when no honey-dew was being gathered, I am quite sure that honey-dew is not always the cause of the trouble. We do not care for any samples that will make bees sick. Thanks for your kind offer, however.



He that is faithful in that which is least, is faithful also in much.—LUKE 16:10.

MYSELF AND MY NEIGHBORS.

THE OHIO STATE FAIR AT COLUMBUS; A GOOD DISPLAY OF HONEY, ETC.

IT seemed almost impossible this year that I could visit the State Fair at all; but perhaps it may be worth something to you to know how much can be done in a short time. The finishing of our new factory, putting in the new machinery, etc., requires my presence almost constantly; but the workmen finally concluded I could be away one day, without making very much trouble. Accordingly, Neighbor H. and I figured up that, by making a very early start in the morning, we could strike the train at a station about 16 miles distant, so we could reach Columbus about one o'clock in the afternoon. To get home that same night, we were obliged to take the train again at 5 P.M., and make another buggy-ride across the country, between the small hours of 11 and 1 o'clock at night, giving us just four hours on the fairgrounds. Well, we planned every thing so that nothing should interrupt us during these four hours. We took a lunch on the cars, so as to be ready to go through the grounds with a rush; and I confess I rather enjoyed my hasty visit. Our new fairgrounds, near the Experimental Farm, are a wonder. Forty-one beautiful spacious buildings contain the exhibits, farm stock, etc., and the architectural beauty of these buildings was, to me, simply a wonder. They cost a pile of money, it is true; but I think the State of Ohio can well afford such an investment for the encouragement of her rural industries. Of course, they don't have any beer on the Ohio Fairgrounds, and the railroad companies have helped to manage the thing so that the beer-men have not been able to get a saloon very near the entrance. The saloons were fewer in number, and smaller in dimensions, than they were a year ago, and it really looks as if they were going to get ashamed of themselves, and vanish from the presence and sight of an intelligent Christian people.

The honey display was finer than any thing I had ever before seen in the State of Ohio. I would call especial attention to the display of both comb and extracted honey by Mr. W. S. Goodrich, of Worthington, Franklin Co., Ohio. The display was very large, and the honey had a crystal clearness that astonished everybody.

"Friend G.," said I, "I suppose this is, of course, clover honey; but how do you account for its beautiful light color and transparency?"

"Why, Mr. Root," replied he, "if I have made no mistake, this whole crop of honey is from *alsike clover*. The drought was so bad that white clover was almost used up, and I am afraid I should have had no honey-crop at all had it not been for my eight acres of alsike."

I give this for the encouragement of those who are thinking of raising alsike as a forage and honey plant. We have had abundant evidence of its worth for hay for milch cows, and now it seems as if it would really pay to raise it for honey alone.

Our good friend Mrs. Jennie Culp was

moving about among the bee-men and bee-women, and she laughingly told me she had *200 gallons* of beautiful clover honey this season. She had it stored in stone crocks, and the crocks were making her a deal of trouble by bursting open as the honey begins to candy. Did you ever hear of such a thing?

Mr. Earl Flickinger also made a very fine display; and one thing that pleased me about his exhibit was, that his good wife stayed behind the railing, and answered questions and explained things.

Our old friend Aaron Benedict was a little in the background, talking bees to people who were curious, while a swarm of nicely marked Italians hung from his whiskers.

One pleasant part of it to me was, that the comb honey was stored in sections of our make, and the sections were mostly neatly incased in bright new cases of our make. Much of the liquid honey also was exhibited in jars, pails, and tumblers bought from our establishment.

I have not space here to tell of the many kind friends whom I met, and who seemed rejoiced to see me, even for only four hours. Have I any *right* to let business keep me away from seeing these *neighbors* at least once a year — these *Ohio* neighbors of mine? A bevy of ladies expressed a desire to shake hands with the editor of Gleanings; and after we had had a pleasant talk, one of them made a remark that carries with it something of a moral. She said, in substance, "Mr. Root, much as we prize Gleanings, I am ashamed to tell you that we carelessly omitted to renew our subscription, and we are not having it this year at all. It was allowed to stop through pure neglect."

In the last *Prairie Farmer*, Orange Judd speaks of meeting old friends in the Far West, during his travels, and he says he met hundreds of people who said the same thing about letting the *American Agriculturist* drop when he was editor. They really valued the paper, and had no idea of letting it stop coming; but it was put off, month after month, and finally they didn't have it "at all any more." Now, I didn't feel like urging these good friends of mine to hand me a dollar just then and there, under the circumstances, that I might send them our journal again; but it occurred to me that the proper way was to have some friend of Gleanings go over every neighborhood, take the money and forward the names; and, of course, the one who does this ought to have pay for it. Accordingly, we furnish Gleanings to such an agent for only 75 cents each; that is, for collecting the names of all those who would be likely to subscribe at *your postoffice*. The supply-dealer of the neighborhood would be, obviously, the party to do this. How shall we get this started? Well, now, dear friends, I do not know any better way than to ask you to agree among yourselves who shall be the agent at your postoffice, and let him look up all the parties who really want Gleanings, but don't like to write a letter, etc. One-fourth of the amount of money received would, I think, pay well for the trouble of visiting them in their homes, and making a neighborly call.

At our Abbeyville Sunday-school, a few weeks ago, the attendance during the hot weather got down to as low as 17, I think. I gave the children a little talk, and asked them how many would really try to bring somebody else to Sunday-school the next Sabbath, in order to keep our school from "dwindling" — not from *spring* dwindling, but from *mid-summer* dwindling. Up went a lot of hands, and I knew by the smiling faces that the work would be done. Next Sunday our seventeen had increased to *forty*. Now, friends, I do not often urge you to help to increase the subscription-list of Gleanings; but the larger the list, the more money can we afford to expend in engravings, and in traveling to hunt up valuable facts for you. Besides helping your paper, you will get better acquainted with *your* "neighbors" by going round among them in the way I suggest; and what is there more more important in this world than pleasant relations between "*ourselves* and our *neighbors*"?

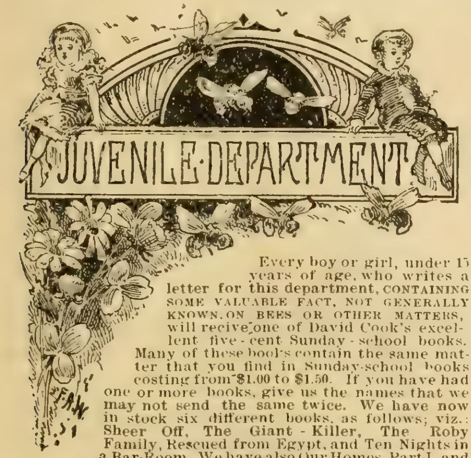
FULL SHEETS OF FOUNDATION, VERSUS STARTERS, FOR BROOD-COMBS.

EXPERIMENTS IN REGARD TO THE SAME, AS REPORTED BY A JUVENILE.

We got only 302 lbs. of comb honey, and increased from 34 to 53. We followed Mr. Hutchinson's plan in hiving 16 swarms; viz., on five empty frames with narrow starters, a queen-excluding honey-board, and a case of 28 sections filled with foundation. We should have had better results if the season had been good. All the swarms went at once to work in the sections, and the combs in the brood-chambers are nice and straight. Nos. 7, 11, 14, and 16, had no drone-comb. Nos. 2, 5, 10, 12, 13, and 15, had each from three to six inches square of drone-comb. No. 3 had nearly all drone-comb; lost their queen, and had fertile workers. Nos. 4 and 8 had each about one-half of drone. Nos. 1, 6, and 9, had each nearly one whole frame of drone-comb. We don't know the age of the queens. Papa wishes some way could be found out to prevent the bees from building so much drone-comb. Would drone-fdn. in the sections prevent it? Cora Major.

Cokeville, Pa., Sept., 1886.

The report of your experiments is valuable indeed, as it is just the point at this time we are all eager to know. Your experiments seem quite favorable to friend Hutchinson's position of the limited or nonuse of foundation in the brood-chamber. Still, from results as above recorded, I think I should prefer full sheets of foundation, unless something can be done to exclude, or at least more nearly exclude, the drone-comb. Perhaps the difference in treatment of the several colonies might obviate the difficulty. Well, supposing we can obviate said difficulty, how are we to prove that the exclusion or partial exclusion of foundation in the brood-chamber will be any cheaper than full sheets of foundation, since able experimenters disagree so widely as to the original cost of wax, as adduced from the consumption of honey. The result of your experiments is so carefully given, friend Cora, that we will send you any thing you may choose, from the 25-cent counter. If any of the other juveniles can report upon the above question, we will do as well by them. In regard to your last question, I should be inclined to believe that the use of drone-fdn. in the super would make little if any difference in the amount of drone-comb built below, though I can not say from experiment. Perhaps friend Hutchinson can clear up some of these things. ERNEST.



Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will recive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from $1.00 to $1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

> "A chiel's amang ye takin' notes,
> An' faith, he'll prent it."

THE LANGUAGE OF BEES; A TALK TO THE LITTLE FOLKS ON BEE-TALKS AND "OLD HEN" TALKS.

I HAVE been telling you something of the way in which bees talk; but bees are not the only dumb friends (if, indeed, I may call them dumb) that have their way of talking. Did you ever hear your old biddy sing? It is true, she does not make very much music, but she is happy—yes, happy as a bee when he sings forth his notes of rejoicing while in the clover-fields. Old biddies not only sing, but scold. I dare say you have tried to put your hand under an old sitting hen. What does she say? Something to this effect: "If you don't get away right off I will—well, peck." How her eyes do snap, and her cluck, cluck, has no uncertain sound. That big old rooster, so big and so proud, how he does strut, worse than Johnnie when in his first pair of pants! and as he mounts the fence he crows forth his challenge to all the other roosters, "I am monarch of all I survey." When one of your nice biddies comes off the nest just after laying an egg, what does she say? "*Cut, cut, cut, cut, ka-dar, cut;*" or, in our kind of talk, "Look, look, look, look what *I* did." Another hen, a little jealous, perhaps, replies, "*Cut, cut, ka-dar, cut,*" or, "Well, well, what of it?" The old rooster, if he feels like it, thereupon claps his wings and—"*Cock-a-doo-dle-do!*" or, "What great things *we* can do-o-oo!" Perhaps your mamma may think I am a little fanciful. Well, perhaps I am in this last; but I think we will all agree that our old biddies can talk, and that right plain. For instance, the mother of a brood of chickens, on seeing a large bird or hawk fly over, utters a shrill cry, at which the chicks may be seen to skulk off. When the old hen espies a mouse or snake in the grass, she will utter a different note. The chicks, instead of hiding in the grass, will stretch their little necks to see where the danger is. When the old biddy finds a choice morsel of food, she calls the chicks to her. It has been estimated by a prominent writer on poultry, that chickens have as many as twenty different signals, or ways of talking to each other. Little folks, can you understand all these signals? Did you ever see how an old rooster talks to his hens? It is real funny. As I have told you, bees have their signs—or, if you please, their language, by which they can express all their little wants, needful for their purpose. The rooster crows, the hen cackles, the queen-bee zeeps; the bee, by the peculiar behavior of his wings and body, gives signals, each of which is intended for a purpose, and which is understood by his kind. God has kindly made all his creatures to know and understand each other.

Now, little folks, I want you to watch and study the actions of bees and chickens, or of any of God's creatures. Learn how they talk to each other, and tell us about it in GLEANINGS. You will then see how *well* God has done his work. ERNEST.

HOW A HORSE WAS SAVED FROM BEING STUNG TO DEATH.

Last spring pa had a horse plowing in the garden, near a hive of bees on the opposite side of the fence, and all at once they almost covered the horse, Charley, and nearly stung him to death. Pa took one pound of soda and dissolved it in water and rubbed him well with it, and in a short time he seemed to be easy. The horse is well now, and as fat as a butter-ball. Pa has 26 colonies of bees and 17 Simplicity hives. This has been a bad season for honey, as it has rained nearly all summer.

Shubuta, Miss. BELL LOCKETT.

A friend two miles distant had his horses stung so badly that he feared they would die. He did nothing for the horses and they got well. ERNEST.

MAKING A BEE-HOUSE BEE-PROOF.

Pa has 30 colonies. He had but one swarm this year. The bees did not do as well in the spring. When the peach-bloom was just opening there came a snow and killed the blossoms. But they are gathering honey off the cotton bloom. Pa has a bee-house, on the inside of which he has pasted paper all over to make it bee-proof. He has a wire door that shuts on the inside, and a wooden one on the outside. When he wants to extract his honey he gets inside and opens the wooden door and shuts the wire door. Pa likes your journal. I like to read it too. ELIZA MARTIN, age 10.

Mark, Sebastian Co., Ark., Aug. 18, 1886.

THOMAS HORN.

Pa had eight colonies of black bees, and he did not winter them. He lost them all, so my three brothers sent for a colony of Italian bees to Thomas Horn. They say they are better workers than the blacks. Pa says it is the best colony we ever had, and he thinks Thomas Horn is an honest man. Pa never heard of such a thing as horned toads, and he would like to know what they are. He says he thinks they are not the kind that we have around here, for he thinks Mr. Root would not keep them in his apiary, for they eat bees.

LENA ZEHR, age 13.

Indian River, Lewis Co., N. Y., Aug. 8, 1886.

Thank you. We are very glad to hear a good word for Thomas Horn; but so many complain of him as dishonest that we warn our friends against purchasing of him. Your logical connection, as the big folks say, between Thomas Horn and "horned toads" is rather abrupt, is it not? However, we have had only one horned toad in our apiary, and that simply as a curiosity. I can not say as to whether they would do much if any harm in larger numbers.

ONE QUEEN SWARMING SEVEN TIMES.

Papa has a queen that has swarmed seven times this summer. He has 32 hives. My brother has a hive of bees, and he likes to go out and look in the hive. Sometimes I go out and help papa when he has a swarm. Papa bought a dollar queen of you last year, and it swarmed and went to the woods 18 days after. He bought another this spring, and it swarmed three times, but died in front of the hive the last time. The kind of shade-boards we like best are made out of old barrel-staves. We use two pickets to rest on the hives, and nail the staves on them. We make two out of one barrel. MAMIE G. STOW, age 10.

South Evanston, Cook Co., Ill., Aug. 29, 1886.

Well, Mamie, if I had a queen that had swarmed seven times, and should give promise of doing as bad or worse next season, I would—well, kill her and put one in her place that would "stay at home" better. It doesn't pay to fuss with such queens, if their everlasting inclination to swarm can not be stopped by some reasonable means, such as more room, more shade, or better ventilation. ERNEST.

WHEN A SWARM ISSUES, DOES THE QUEEN ALIGHT FIRST?

When a swarm issues, does the queen generally alight first, or the bees? You will notice on page 302, May GLEANINGS, Mr. Brayman said he lay by the hive watching for the queen, while his wife watched where they were going to cluster; so I take it from that, that the bees commence to cluster before the queen.

GRAHAM S. DEWITT, age 11.

Homowack, Ulster Co., N. Y.

My young friend, I think that the bees, as a rule, alight first, and the queen when a part of them have commenced to cluster—at least I have watched quite a number of swarms while clustering; and when I have been able to get my eye on a queen it is, as a rule, when they are about half clustered. Young queens are especially apt to be running out of and in the cluster, taking wing, and then coming back again.

13,000 LBS. OF HONEY FROM 200 COLONIES; HOW TO MAKE A HARVEST DRINK OF HONEY.

Pa has over 200 colonies of bees. He has extracted over 13,000 pounds from them this season. It has been very dry weather here for quite a while, and the white clover has nearly all dried up. I will tell you a way of making a drink that is better than to drink so much cold water on these warm days. Take 1½ teacupfuls of honey; ⅔ of a cup of vinegar, and one heaping teaspoonful of ginger, to a gallon of water. We call it "ginger ale." Pa's bees are not gathering much honey now.

GRACE POPPLETON, age 14.

Williamstown, Iowa, July, 1886.

Well done, Grace. Your home-made ginger ale, I should think, would be tiptop; but isn't half a teacupful of honey to a gallon of water making it pretty sweet? When one is tired and thirsty, some sort of a drink with sweetening in it will give strength and energy almost immediately, as I know by abundant experience; and the ginger seems to have the effect of making the drink "set well," to use a common expression. If our summer beverages never have any thing in them more dangerous than vinegar and ginger, I think we shall all be on pretty safe ground.

LOOKOUT MOUNTAIN, AGAIN; THE EFFECT OF THE DIFFERENCE IN ELEVATION UPON THE LENGTH OF THE HONEY-FLOW.

You ask in GLEANINGS if the honey season was prolonged on account of the elevation. Our experience is the same as the writer who mentioned that subject before. The clover and other honey-plants come in 14 days earlier in Chattanooga Valley than up here. This mountain is 1800 feet above the valley. Our bees have swarmed three times since I wrote to you June 20th, and we have now 14 swarms of pure Italian bees. They have taken a great deal of honey from the sourwood, and are now very busy on the wild-flowers. There have been two great battles fought on this mountain—one on the 28th day of October, 1863, in which action Gen. Joseph Hooker gained the mountain; and on the 23d day of November, 1863, the Union troops under Generals Hooker, Thomas, and Sherman, drove the Confederate troops under Gen. Bragg off the mountain. The last action was the fierce "Battle above the Clouds." Many marks of this battle remain in the shape of forts, camp-chimneys, rifle-pits, and breastworks. A line of breastworks extends along the northern side of our apiary, and form a windbreak for it. I live at Point Lookout. There are hundreds of people visiting it every month. There are many points of interest on the mountain, among which are Lookout Cave, Point Lookout, Natural Bridge, Rock City, Lake Seclusion, Lulu Falls, and Eagle Rock. The air is very light and healthful.

GEORGE LAWSON.

Lookout Mountain, Hamilton Co., Tenn.

Thanks for your description of Lookout Mountain, so famed in the history of the late civil war. The natural scenery, together with the remnants of that remarkable conflict, fills me with a desire to visit that place at some future time. ERNEST.

MAKING PRESERVES WITH HONEY; HOW A SEVEN-YEAR-OLD HELPS PA.

Pa has taken GLEANINGS for years, and I like to read the little children's letters. Pa has 40 hives of bees. I help extract. I carry the honey to and from the extractor. Ma uncaps, and pa takes the frames out and brushes off the bees. Pa made a solar wax-extractor, and it works well. Ma made blackberry and apple preserves with honey, and we like them. We like the apple preserves better than if they had been made with honey, and it is good enough for a wedding-cake. We can not tell it from sugar-cake. **ALLIE SHUMARD**, age 7.

Panacea, Mo., Aug. 4, 1886.

Thank you, little Allie. We like to hear of all the different uses to which honey can be put.—When I was seven years old I was "afraid of bees," and my pa could hardly persuade me to help him to extract. What a coward I was, wasn't I? **ERNEST.**

HOW TO MAKE A QUEEN-CAGE, AS DESCRIBED BY A JUVENILE.

This is my first letter. I caught a bee and pulled its sting out. It lived 29 hours and 32 minutes. To make a cheap queen-cage, take a block of wood 1½ inches high, 1¼ inches wide, and 2 inches long. With an inch auger, bore a hole close to one end (on the 1¼ side of the block) 1¼ inches deep. Take a ½-inch auger, bore from the other end until you strike the other hole. Tack a piece of wire cloth over the large hole. Take a thin piece of wood, bore a small hole in it, place it on top of the wire; fill the ½-inch hole up with candy, and place a plug at the end. **VIRGIL H. MOATS**, age 13.

The Bend, Defiance Co., Ohio.

Your description of how to make a queen-cage is pretty well done, Virgil, and I think we can "catch on." The cage is something on the plan of the Benton cage. **ERNEST.**

TOBACCO COLUMN.

THE FRUITS OF THE TOBACCO COLUMN.

WELL, Brother Root, I have not forgotten you, although I have not thanked you for the smoker you sent me last year. I am very much obliged. I have kept my resolution so far. It has been over a year since I quit the use of tobacco, and I have had no appetite for it; and by the help of my Lord and Master I never shall use the vile stuff again.

We have had a very dry season—the dryest I ever saw. Every thing is dried up. We shall have but little hay and oats. Bees have done poorly. They have swarmed but very little. If we do not have rain soon I shall have to feed for winter. Buckwheat that was sown 3 weeks ago is not up yet. We had a little shower to-day that may bring it up. Basswood did not bloom at all this year. I feel almost discouraged, but I put my trust in Him who is able to help us in every time of need.

Orono, Mich., July 13, 1886. **L. REED.**

Seeing your generous offer in GLEANINGS to those who give up the use of tobacco, I have joined the throng that claim the reward (the smoker). If I ever resume, I agree to pay double price for the smoker. I used the weed for over six years.

LEVI E. MALLERNEE,

Cerro Gordo, Ills., July 5, 1886.

Please send to Elmer Divens, Good Hope, Fayette Co., O., one bee-smoker, for quitting the use of tobacco. He agrees to pay cash if he fails.

Good Hope, O., June 23, 1886. **B. R. PAXSON.**

A BROKEN PLEDGE, BUT PAYS UP.

Charge me with 50 cents for a smoker on tobacco pledge for my brother, as he has broken his pledge.

Arcadia, Kan., July 8, 1886. **S. C. FREDERICK.**

I have quit the use of tobacco. If you will send me a smoker, and I ever use tobacco again, I will pay you for the smoker. Bees are doing better than ever before. **W. J. HESTER.**

Eureka Springs, Ark., July 2, 1886.

I am an old tobacco-user, and by reading the Tobacco Column I have resolved to quit; and as sure as ever I resume, which I pray I never shall, I will send the price of the smoker. **J. C. SLOCUM.**

French Grove, Ill., June 25, 1886.

Some neighbors of mine to whom I read GLEANINGS regularly, and who feel great interest in bees, and who are bee-men in the old-fashioned way, have, by my wish, and through my persuasion, forsaken the use of tobacco for more than one year now. They have given me their word never to smoke or chew again. Please send them a smoker each; and if they break faith I will pay for them.

FELIX W. O. SCHMIDEL.

Fort Ogden, Fla., June 15, 1886.

INDUCES A FRIEND TO QUIT; ALSO A KIND WORD.

I received the goods the 25th of May in good order. I am well pleased with my frames. I have the 300 frames nearly full of comb and honey. I never saw such a honey season as this, in all of the 17 years of my bee-keeping. There is a young bee-keeper here whom I induced to stop using tobacco. I told him if he would never use it again you would send him a smoker. Will you please send him one? I will pay for it if he uses tobacco again.

GLEANINGS is the best of all the papers I am taking, and I take eight different ones. Our Homes is my best reading. I hope, friend Root, you will have a long and happy life. May God bless all your teachings. **JOSEPH SOPH.**

New Haven, Mo., June 26, 1886.

HEALTH IMPROVED.

I have used tobacco since I was five years old, and I don't know when I did commence the use of the weed. I used it the day I started to school, and, feeling it to be a sin against God, and knowing it in no way prepared me to live a holy life, or to serve God in any way, by his grace I have quit it, and am in better health than I have been in for twenty years, and I enjoy more of the presence and fullness of our blessed Lord; so if you have determined to contribute a smoker to every one who quits, you can sell the smoker and invest the amount in religious tracts, and distribute them for the good of humanity and glory of God; and should I use it again I will let you know, and pay you double price for the smoker. **L. W. MILAM.**

Prescott, Ark., June 19, 1886.

Friend M., I have heard it said, that in the Southern States it was customary for school children to use tobacco; but I did not know before that they ever commenced it at so early an age as five years. Thank you for your kind and encouraging words.

I understand you will give a smoker to all who will quit the use of tobacco. I will abandon the use of it if you will send me one. I give you my promise to pay for the smoker if I ever use the weed again.
Lonegum, Va. T. A. Wood.

I see you give a smoker to all who will give up tobacco. I promise to stop; and if you send me one, and I should break my promise, I will send you the money for it. Vischer Whipple.
Porter's Corners, Saratoga Co., N. Y., July, 1886.

My brother says you give any one who quits tobacco a smoker. I used it fourteen years. If you think I am entitled to a smoker, send it; and if I ever commence I will own up and pay for smoker.
Oak Bower, Ga., June 29, 1886. A. H. Vickery.

I used tobacco a great while, but have stopped it. A friend told me that you would send a smoker free to any one who would give up the use of tobacco. If you will send me one I will never use another speck; but if I do I will pay the full price of the smoker. Frank A. Padgett.
Jacksonville, Ill.

HAS USED TOBACCO 55 YEARS, AND NOW QUITS.

I see much in Gleanings about your giving a smoker to those who quit the use of tobacco; but as I do not use nor ever have used it, I can not stop the use of it. But my grandfather, who began its use when four years old, and has kept it up for 55 years, has at last quit, and he is now fairly angry whenever he sees anybody using it. He said that I should ask you for a smoker; and if he ever uses the vile stuff again, and does not pay for it, I will. A. H. Abel.
Ironia, N. J.

I found a notice, stating that you would give a smoker to any one who had quit the use of tobacco. I think that I am entitled to the smoker, for I have been a habitual chewer and smoker. I used one pound of the best fine-cut in 15 days, and smoked about the same amount of smoking-tobacco, and occasionally a cigar. It has been some time since I quit; and if you see fit to send the smoker to my address, I agree to give you $1.00 for it if I ever use tobacco again. I have 18 swarms of bees, and they are doing quite well, although it has been very dry here this summer. I am much interested in bee culture. I handle my bees without any protection whatever. R. H. Peet.
Hebron, Pa.

My brother-in-law does not think you are reliable; and when I told him what was on the card I had just received, and asked for the promise in his own handwriting, as you asked for, he said something about like this: "He will never send it; you and he will keep writing to one another until you pay out more than it is worth. You are out 20 cents now, and I don't believe you can get him to send it, if I were to write the promise to him. I wouldn't fool about it any it any longer. I should like to have the smoker, and would consider it as a reward, but you'll never get it for me in that way" (this last rather positively). "If he sends it, though, I will stick to my promise. There has been a month's delay, and I believe I will buy one." And off he went about his work. Now, Mr. Root, I don't blame you for wanting things fixed exactly, "so there is no creeping-hole;" and if you are minded to publish this, and send him a smoker, you can do so.
Clear Creek, Ind. A. H. Tering, Jr.

You say, if I quit on account of your offer, etc. I was persuaded through Gleanings to quit. I quit because it was right, and tobacco is injurious to my health, and not for money; but I was influenced by you to quit. H. S. Collins.
Mayville, Mich.

A friend of mine quit the use of tobacco in order to get a smoker. He has not used it for 3 months, and says if he uses it he will pay you $1.00 for the smoker, and I will give him the extra one I got of you if you will give me a new one. A. L. Light.
Grove Land, Ark.

I received the queen all right. I did not know there was any such promise required for the smoker; but I will promise to pay for it if father begins the use of tobacco again. I also indorse the promise. C. M. Kellogg.
Dallas, Wisconsin.

KIND WORDS FROM OUR CUSTOMERS.

I received the A B C book all right, and like it. I don't see how you can sell such a book so cheap as you do. H. S. Payne.
Richmond Corner, Me.

THAT FOUNDATION.

The comb foundation was received all right. Thanks for prompt shipment. It is nice foundation. The cells are deep, and it is altogether good, better by far than that I used before (flat-bottom).
Carlstadt, N. J., Aug. 20, 1886. F. Holtke.

[See article on p. 728 in regard to flat-bottomed fdn.]

A DOLLAR WELL INVESTED.

The A B C book I got of you is a handsome prize, and I think it is just "immense" pleasure to peruse its well-printed pages. One of my friends said that the dollar I paid for it was the best invested that he ever knew a dollar to be in printed matter. A. H. Abel.
Ironia, Morris Co., N. J., June 16, 1886.

OUR WHEELBARROW FOR BEE-KEEPERS, AND WHAT A PRACTICAL BEE-KEEPER THINKS OF IT.

The wheelbarrow ordered from you on the 1st arrived on the 4th, and I must say that it is far ahead of any thing I have ever seen in the shape of a light wheelbarrow, even at a much higher price. It is both strong and light, and I should say durable, and just what a bee-keeper needs. I have thought for some time that I would have a light spring wheelbarrow made, but could not get one up for much less than $10.00, while this one at $4.50 entirely fills the bill. You are certainly to be commended for placing such a convenient article within such easy reach of bee-keepers and the public generally.
Wyoming, N. Y., Sept. 6, 1886. G. W. Stanley.

[Many thanks, friend S. We feel assured that the bee-keeper's wheelbarrow will stand all you say.]

HOW GLEANINGS PLEASES.

Inclosed find $1.00 in payment of renewal of my subscription to your valuable and by me much-prized Gleanings for the ensuing year. It has been an ever-repeated pleasure to me, and I have profited greatly by its plain and comprehensive articles, and always waited for the arrival of each successive number with almost impatient interest to see what treat you would give us in the next, and it never failed to satisfy my expectations. It is really one of the pleasures and delicacies of bee-keeping, if I may so express myself, having so many different subjects on occurrences in life, and how to take and overcome them, as well as talks and suggestions regarding neighbors, household, and family, blended together in so pleasing a manner that I like it all the more. And now wishing Gleanings and its staff of editors and co-workers success in their noble work, I am your friend,
Newark, N. J. Chas. H. Theberath.

[Many thanks for your very, very kind words, friend Theberath. It does us a "heap of good" to feel that our efforts are not only appreciated, but are bearing a little fruit for the Master.]

OUR HOMES.

Have the gates of death been opened unto thee? or hast thou seen the doors of the shadow of death?—JOB 38:17.

I PRESUME most of the friends have gone over the accounts of the events of the recent earthquake, and doubtless quite a few of the readers of GLEANINGS have had more or less personal experience of this event that has aroused the attention of every thinking man and woman of our land. Perhaps more than one earnest Christian has felt troubled, at times almost lost, in the effort of trying to comprehend why the loving heavenly Father should permit such disasters to occur; and I may as well confess to you frankly, dear readers, that I feel at the outset that it is a task far beyond my capacity or capabilities, to even *attempt* to handle the subject. May God in his infinite love and wisdom bless and direct my feeble words.

In considering the matter, and in reading it up that I might be able to talk to you in regard to it, I have felt my comparative insignificance as I perhaps never felt it before. A few days ago Huber and I were sitting hand in hand, watching the setting sun. He turned to me and asked in his childish way:

"Where does the sun *go*, papa?"

Now, do you wonder that I did not answer him immediately? I do not know but that he repeated his question two or three times before I felt able to give him any kind of a rational or consistent answer. Should I tell him the sun didn't go at all, but that the world on which we live turns around toward it? This would be the only really truthful answer, in one sense; but it was beyond his comprehension; and, furthermore, do we really *know* that the great sun *is* standing still? The intelligence of the world made a great stride when it decided that it is the earth that is constantly moving, and not the sun; but who shall say what the next great stride may unfold? The opportunity was an excellent one for teaching my boy, and I would by no means pass by such a query unanswered; but I felt as many a parent has felt before, that my answer must be suited to the capacity of my pupil.

Did it ever strike you, my friend, how many times Jesus, in teaching his disciples, told them kindly and lovingly that they were not yet able to understand the things of which he spoke? Toward his approaching death he tried to teach them self-sacrifice, and that it were better for them that he should die the death of a malefactor. They seemed, however, so utterly incapable of grasping the great thought of atonement, that he stopped or decided not to go any further just then. He says, "Ye can not bear them now," giving them to understand, evidently, that the time would come when they could not only bear but understand these great truths. How true it was in the case of Peter! Contrast the man as he was during his evangelistic work, with what he was before he denied his Master, when he so stoutly insisted, that, though all men should turn away, he would not. Well, Huber will doubtless be able, some time, to be taught astronomy; but it would be folly to think of trying to explain much of it to him now. I spoke to him something like this: "My boy, the sun goes down behind the trees, clear out of sight; then in the morning this same old sun comes up back of the trees away over there. Don't you remember?"

"Oh! yes, papa; I know how it is now." And then he was full of childish prattle and other things. By and by I can teach him more of the movements of God's great luminaries, but not now.

Is it not so, my friends, in regard to earthquakes? God is teaching us by great lessons, sometimes by terrible lessons, and oftentimes we come to the boundary of human capacity and intelligence. We not only can not understand, but, what is of much greater moment, we can not *bear* to be *told* the things he would tell us. We look aghast at the thought of sudden death; and even some who profess to put their whole trust in Him who has but to speak, and the winds and the waves obey him, stand terrified with trembling faith as they behold the apparent confusion of the elements. Does God really have any thing to do with earthquakes? Most surely he does. They are part of his plans from the beginning; and before we reject the teachings of his holy word, and rebel against the laws of the all-wise Creator, suppose we consider a little this matter of life and death—that is, so far as we are able to consider it.

In our opening text, God reproves the murmurings and complaints of Job and his friends. "Have the gates of death been opened unto thee? or hast thou seen the doors of the shadow of death?" It seems hard to see men, women, and children, perish by earthquakes, by storm, by cyclone, or by flood. We have become somewhat accustomed to the storm and to the flood, so that they do not strike us with the great horror that we feel when the solid earth under our feet seems to be solid earth no longer. I have been told, that it is impossible for human tongue to describe the awful sensations awakened when one realizes that the very earth itself is rolling and shaking beneath our feet. Once when seasick on board of a steamer, I so longed for the solid ground that I made up my mind that I would get off at the first opportunity, no matter where I was, nor what solid ground I found. With pallid cheeks, and tear-stains down my face, I pushed my way along the plank. One of the officers of the boat called after me, and told me that I was getting off at the wrong point. I told him I could not help it; I was going to get off, right or wrong.

"But," said he, "you can never get anywhere if you stop here. There are no railroads nor any thing else."

I told him in that case I should stay there always, and be happy; and when I felt stationary ground under my feet it seemed to me then that I could ask for nothing more, providing I could feel this solid ground always. Perhaps I can realize a little what it would be to find even this old earth an uncertain foothold; and may God help me to sympathize with the brothers who have recently suffered. Death seems to us terrible in this shape, because it is comparatively new to us. We have been congratulating ourselves during all these years, that earthquakes did not visit our locality, or, at least, that the visitations are so far between, and so feeble when they do come, we might consider ourselves comparatively exempt. The events of the past few days teach us differently. Great forces are at work under our feet, that we dreamed not of, and our whole continent is liable at any moment, or at any hour, to be rolled and tumbled about like the waves of the sea. After the great Chicago fire, men talked of building houses that would withstand the devouring elements; but what architect or mechanic shall think of planning a building that will be secure against earthquakes? The idea is folly. The conviction forces itself upon us, that there is no place exempt from devastation and death and ruin. No place? Yes, thank God, there is a place of refuge. We are told in the Holy Scriptures, that, although heaven and earth should pass away, God's words shall not pass away. I do not mean, mind you, that the Christian shall be spared the pangs of death, or that he shall be passed by when the devouring elements come; but I do mean, that grace and strength will be given the one who puts his whole trust in God, so that he may bid defiance even to calamity and death. "My grace is sufficient for thee," is what the Holy Spirit told Paul when he besought God to take away the thorn in the flesh. But the thorn remained there still, and to the end of his life, to buffet him.

The question has sometimes been asked, why God should permit innocent, helpless women and children to thus suffer and die. My friend, the helpless and the innocent suffer and die by disease, and have suffered and died since time began. I presume the sufferings and death caused by an earthquake are not to be compared with the sufferings caused by disease. Disease is all round about us; we are familiar with it; and for some reason, perhaps not quite explained, most of us would prefer to die a slow and lingering death by disease, rather than a sudden death by accident; this feeling is perhaps largely caused by weakness—more largely by want of faith. It is true, that a faithful, trusting follower of the Savior is sustained by a Savior's love, and enabled to bear the pains and sufferings of disease; but is it not true, too, dear friends, that the faithful Christian has grace and fortitude given him to face death and torture unflinchingly, even though it comes by accident, or in the discharge of regular duties? I think he has, and yet I have asked myself the question over and over again, whether *my* faith in God's loving care is such that I should not get demoralized and frightened, and behave myself in a manner unworthy of a follower of the Lamb. May God help me to endure trial when the trial comes!

We are told by the papers that meetings were held in Charleston, and that groans and prayers were sent up to the Father, beseeching him to spare them from further shocks of the earthquakes. But still the shocks went on. Shall we not bear in mind that even the prayers of the Son of God for deliverance from the cup that stood before him were not granted? It is true, he ended with "Nevertheless, not my will, but thine, be done." But what mortal is there among us who could have the grace to say, when death faces him, "Thy will, not mine, be done"? And were these prayers that were offered up then in accordance with that spirit? When in sore trouble, or amid intense pain, it is human and natural to ask simply for deliverance—nothing more. My friend, did you ever think of it, that, when you ask God to deliver you from the pain and trials that fall to the lot of average mankind, you are asking to be an exception to the general rule of humanity? In that light, is it not a selfish one? Can you be a consistent follower of Christ, and ask that your path may be easy and smooth while your fellows are suffering all round about you? In our little home circle, the younger ones are prone to drift into selfish ways if they are not carefully taught and guarded. Sometimes Huber, in the exuberance of his spirits, sings out as soon as we get to the table, "Give me some strawberries. I want some strawberries. Mother! mother! give me some strawberries!" And this request is often made before any one at the table has been served at all. Sometimes I try to show him his selfishness by a reply something like this: "Why, my boy, do you want some strawberries when neither cousin Mabel nor any of the rest have had any at all?" Now, even though Huber can not understand the truths of astronomy very well, he can be taught the beauty of a self-sacrificing and Christian spirit; and he usually hangs his head with a look on his face that indicates that he feels ashamed. When pressed for an answer, he speaks up like a man, and says, "Wait on cousin Mabel first." Now, then, dear friends, are not our prayers for deliverance too apt to be like the request of the little one for strawberries? We want to be waited on first; we want the best of every thing ourselves when there is a choice of best.

One of the daily papers, a few days ago, was commenting on the different people who travel in our railway cars. The paper spoke of the fidgetty, nervous people who are unused to travel, and have to be making constant inquiries as to what to do and how to act. Then they contrasted them with the class who make a regular business of traveling—the commercial class, for instance. Well, they said this latter class would be off the train almost before it had stopped. If there were to be twenty minutes for dinner, they were first to the dining-table, and got the best places and secured the best viands before the former class had found out where the dining-room was. If tickets were to be secured for a sleeping-car, they secured all the best berths first, and left the others to do as they could. Now, I hope I am telling the exact truth when I say I don't want the best places when I travel. I hope I should feel ashamed of myself, even if I were smart enough to succeed in getting the best of every thing, and the easiest places. I am sure I am, because in so saying I want to take my chance among the people. If somebody has got to take a poor place, let me be one of them. If I don't realize to the full extent what I am saying while I dictate these words, may God help me to come so near to him that I can say, "Give me not the best of every thing in life, but help me, and give me grace and strength to take some of the hardest places. If pain is the lot of humanity, help me, O Lord, to take my share of the pain and suffering; and when death shall come, whether it be by earthquake, by cyclone, by storm, or by flood, or by slow lingering sickness, help me, Lord Jesus, that through it all I may be able to say, 'Thy will, not mine, be done.' And if death should come with sudden horror, help me that I may be found ready to deport myself as becometh every follower of Him who died for us all."

I presume it is no doubt true, that only a few of us have any real comprehension of the amount of suffering poor humanity is sometimes called upon to bear.

As a general thing, no one thinks of murmuring against God when he dies in a natural way on a sick-bed; but, if I am correct, death by accident or great catastrophes, like earthquakes, floods, and tornadoes, does not compare in suffering with natural sickness. In speaking of some cases of intense suffering, please bear in mind that I do it solely that you may take a fair view of what doubtless lies before many of us. A Christian needs to be brave. He needs to be able to take pain and suffering in a manly, heroic way, and to take it, too, when none are near to look on and sympathize, if need be. Two cases have come to my knowledge, of such excruciating pain from prolonged suffering that the sufferers begged their friends to take their lives, to put an end to their misery. No doubt the poor sufferers had become so exhausted and worn out that they did not comprehend fully what they were saying, and perhaps delirium had something to do with it. It is true, I believe, that it is the lot of some to die comparatively without pain; but as we read that God sends the rain upon the just and upon the unjust, I believe it is also true that he sends terrible and agonizing pain upon the just and upon the unjust. I have not been able to learn that the most sincere and devoted Christian is, as a rule, spared from suffering, because of his devotion to the Savior. In fact, it has sometimes seemed otherwise, verifying the text, "Whom he loveth he chasteneth."

It was my privilege to be near a dear friend and relative a good deal of the time during her last sickness and death. For years before her death she had expressed herself as willing to go when God should call her. Her decline was slow and very painful. For some weeks before she died she would ask wearily what time it was, because the time passed so slowly. She longed for the night, and she longed for the morning; but amid it all, nothing seemed to give her so much comfort as to have somebody read to her from the Bible. I came in one day to read to her, but found the family physician there. Like too many physicians, he was an ungodly man. He stood by the bedside, apparently in no hurry, laughing and joking; but when she asked me to read to her, and desired him to sit down a moment, he excused himself by saying he hadn't time. Now, although she was suffering at the time the most intense agony, she plead with him to listen to a few words from the Holy Scriptures. She did not *forget* her pain and suffering, but she *ignored* it as being of little consequence compared with the wish to do something for his soul's salvation. As the family physician, it was to be expected that *he* could do something to alleviate *her* intense suffering; but although he seemed to treat it as a light matter, she overlooked it all, and seemed only anxious that *he* should be healed. Now, God sustained her amid these sufferings, and helped her to bear them, but she felt the anguish none the less. She never complained nor murmured, although she was one of those organizations that feel pain most keenly. When she was so near her end that she was unable to speak to us, or even to give any sign, it was evident that the poor tortured body was suffering still; and when the last breath was drawn, and exhausted and worn-out nature refused to move any further, it was evident from the expression on her face that the last pang of death was the utmost agony. I knew her so well that I could tell by the movement of her face and mouth when she was suffering, and I think it quite probable (although some physicians may say she was not then conscious of pain) that the suffering of that last brief moment surpassed any thing she had ever known before. When it was over, a placid, peaceful expression settled over the features. She had fought the good fight through intense pain and suffering. She had finished the faith, like Paul of old, and the crown of righteousness was hers.

Now, my friends, far be it from me to frighten any one by the thought of death; on the contrary, I would bid you be brave, and strive to say with the Master, "Thy will, not mine, be done." We are human, and a kind heavenly Father will, without question, make due allowance for human weakness, even should we be tempted to feel, for the time being, that he has forsaken us. It will be no more than what the Master did. Whether it shall come by slow and torturing sickness, or by the swift elements over which we have no control, let us be ready to die as men, and as becometh Christian men and women.

The progress which science seems to be now making would indicate that we are, at least in a measure, at fault for the sufferings of sickness and disease. It may also be true that we are remotely responsible for floods and cyclones; but what scientist dare have the boldness to say that we are in any sense or measure responsible for the dire consequences of the earthquake? It is a matter that is in God's hands entirely. In that case, why should we worry or be afraid? The spirit that prompted the patriarch Job, when he said, "Though he slay me, yet will

I trust him," is what we need; and the chapter from which our opening text is taken will help us toward it. Some of us are naturally timid and cowardly. I have sometimes been afraid that I should fail miserably in living up to my own teachings were I suddenly called upon to pass through such a disaster as many of the friends and neighbors have been called upon to pass through in and around poor Charleston. In a recent number of the *Sunday-School Times* we find the following:

> "It is recorded of John Bunyan, that, once when he was in prison, and uncertain whether he might not soon be condemned to die, the thought entered his mind: 'Suppose God should withdraw himself at the very last moment, fail to support me at the gallows, abandon me!' Then he says he resolved thus: 'If God do not come in, I will leap off the ladder even blindfold into eternity, sink or swim, come heaven, come hell! For it is my duty to stand to his word whether he ever looks upon me or saves me at the last, or not!'"

One is almost inclined to smile at the above; and yet, my friends, does it not embody a wonderful truth? God has placed us here in this world, and paid us a great compliment in making us free—free to step toward heaven or to step down to ruin. Now, shall we not use this freedom to be bold and brave for the right, no matter what the consequences are? We are not responsible for earthquakes; but we *are* responsible for our behavior when God sees fit in his infinite love and mercy to call us to face death and the great unknown beyond.

In conclusion, how much does it matter whether we die now or die ten years later? I once visited a sick man, near to his death, with my old pastor, whom I have before mentioned. The man had (since his sickness) made some profession of religion, although his whole life had been very intemperate and bad. The minister asked him if he would like to have us pray for him. "Yes," he said, "and please pray that I may get well." Now, then, suppose we had so prayed, and that he had recovered, what would he probably have done with ten years more of life? Why, from the talk I had with him, and from what I knew of the man, I felt sure it would have been ten years more of drinking and wickedness; at least, I am safe in saying that the ten years would have been of no sort of benefit to him or to anybody else. In such cases what are a few years of life worth, or what does it amount to?

In a recent Sunday-school lesson we find the text, "If ye abide in me, and my words abide in you, ye shall ask what ye will, and it shall be done unto you." No doubt a great deal of discussion has arisen in regard to this verse. May be I am not equal to the task of handling it; but, dear friends and fellow-Christians, I feel sure of this, at least: That those who are abiding in Christ will never be found begging simply for an easy life, or one of freedom from pain. I do not mean to say that it is wrong to pray that your life may be spared, or that God may ease the pains that rack your body; but is not such a prayer better when put something like this? "Help me, O Lord, to better understand the laws of health and the laws of life, that I may be able to see wherein I have transgressed these laws, that I be thus afflicted. And if my labors in thy vineyards have heretofore been pleasing in thy sight, and if it is consistent with thy holy will that my life should be spared, I pray thee to help me to arise from this bed of suffering. Nevertheless, not my will, but thine, be done." When we ask God for any of these things, we ought to be in such an attitude of heart that we can say, "Thine be the praise and the glory for ever. Amen." If we are abiding in Christ, our prayers are not likely to be selfish or inconsistent; and if they are in the spirit of Christ, God will surely answer.

While speaking of this subject of dreading death, and longing for longer life, permit me to refer to an incident I may have mentioned before. I wish to speak of it because it contrasts so powerfully with what the life of a Christian should be: During a steamboat accident on the Ohio River, great numbers of people were thrown into the water, and many were drowned. Bystanders on the shore gave what aid they could; still many lives were lost in spite of them. Well, during this scene of excitement big strong men were seen to hurl or strike weak women to get them off the planks whereon they had a promise of being rescued, in order that they might save their own lives. Of course, it would not have been safe for those men to land where the people could get hold of them. They accordingly made for the opposite shore, and escaped on planks and ran off into the woods. I can readily imagine that they were intemperate men—gamblers, possibly, may be highway robbers by profession. They did not propose to die, even though a few helpless women *did* have have to be murdered in order to save *their* miserable lives. Contrast such a spirit with that of the self-sacrificing spirit of a Christian. And beware, my friend, that nothing in your life or actions should ever come, even remotely, near to such a spirit. Our lives belong to God. They are his to give and his to take away.

I must not omit mentioning a feature connected with these losses of property and life that seems to have something encouraging in it. At the time of the great Chicago fire, almost everybody was astonished to see the alacrity with people north, south, east, and west, rushed forward to aid the sufferers. Chicago had but to make her wants known, and food and clothing, as well as money, poured in from all sides, until that great city of destitute ones was obliged to say, "It is enough." And this one thing, I am sure, did more to bring about friendly feelings and friendly relations among the people of the different cities of the different States than almost any other thing that could have happened. So far as I have learned, the same thing will be found true for the sufferers at Charleston. Already the mayors of the different cities, and the officers of the government, who have it in their power to send relief, are doing all that rapid communication and quick transit can do. Who knows but that this event may do more toward restoring and establishing on a permanent basis friendly relations between the North and the South than any thing else that has happened for many a long day? In the language of our text, the gates of death have not been opened unto us, neither have we seen the doors of the shadow of death. We know but little of the machinery that governs the universe in this life, and we know even less of the great unknown eternity beyond it. But we *do* know that a kind loving Father in heaven looks down upon us, and that in his own good time his kingdom shall come, and his will be done on earth as it is done in heaven. May he give us grace to say, under all circumstances and conditions, "Blessed be his holy name."

GLEANINGS IN BEE CULTURE.
Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER.
MEDINA, O.

TERMS: $1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, SEPT. 15, 1886.

Where wast thou when I laid the foundation of the earth?—JOB 38:4.

DISCOUNT ON ORDERS RECEIVED THIS FALL FOR GOODS TO BE USED NEXT SEASON.

WE will, during the month of October, allow a discount of 10 per cent on goods ordered now, strictly for next season's use; that is, we allow the above discount for goods ordered now that you will not need to use before next spring. This will include Simplicity hives, sections, frames, honey-extractors, etc.; but it does *not* include chaff hives, glass and tin receptacles for honey, and, with some exceptions, tools and machinery. We make the above discount that we may have something to do during the dull fall months, and to allow you something for furnishing the money now, instead of six months hence.

OUR CARP-POND.

WELL, after all this long time I am glad to be able to say that we have young carp in our pond, so plentiful they look like swarms of bees. They are now from half an inch to an inch in length. I do not know why we have not been able to see the little "people" before, unless it was on account of musk-rats and mud-turtles. Ernest killed the turtles with his gun, and one of our boys whom we call Fred happened to be expert with steel traps. I offered him 25 cts. for all the musk-rats he would catch. It turned out bad for the musk-rats, but it came pretty near filling Fred's pockets with silver quarters.

TERRY'S SYSTEM OF POTATO CULTURE.

WE are just now rejoicing over great large fine potatoes, and almost no small ones in a hill. They are the result of the teachings of the Potato Book. If you should plant a dozen stalks of corn in a hill, you would get a great quantity of nubbins and no corn. Well, my friend, if you put a great many potato-eyes in a hill you usually succeed in getting a large lot of "small potatoes:" whereas by Terry's system you have one large stalk and no more; at the proper distance, another large stalk, and so on, and the result is as you might expect—large fine potatoes, and probably more bushels to the acre than you could possibly get in the old-fashioned way.

OUR NEW BUILDING.

IT is now roofed and inclosed. The engine is in place, set on a bed of masonry that seems as if it might stand the shock of an earthquake—that is, if any thing could withstand such a catastrophe. The shafting and pulleys are ready for their places, and every thing about the whole establishment is to be the best of its kind that the present age affords. Special machinery, built expressly for the different processes of bee-hive making, the results of the experience of many busy years in the work, are to take the place of our old machines wherever they can be bettered. The combined area of the floor room in all the three buildings now measures nearly a whole acre. Counting the barn, toolhouses, and warehouses, it would make fully an acre and a quarter of covered floor room for our hands to work on during stormy weather.

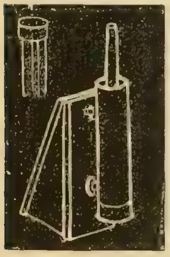
MORE SWARMING OUT.

IT did not happen in December this time, but it happened to be exactly Sept. 1. It was not the queen-clerk this time, and Ernest had nothing to do with it. It was our daughter Maud. The last we saw of her she was going northward, and by and by we heard of her over in Canada. You know, I have always had a warm place in my heart for the Canadians, and now I don't mind telling you why. When Maud started on her trip, one of our Canadian boys, John T. Calvert, whom you have heard me mention, went with her, I suppose for safe keeping. Years ago, when cares pressed, I prayed, as I had often prayed before, for efficient helpers; and by one of these wonderful providences a Christian boy away off in Canada was praying too, for a place to work where he need not hear God's holy name taken in vain day by day. Through GLEANINGS he heard of us and our work, and John has proved himself a blessing indeed in more ways than one. If he is a fair sample of Queen Victoria's subjects, we can in real truth say from our heart, "God save the queen." Ernest and John have been away together at school. When my health threatened to give way, Ernest took hold of GLEANINGS, and John rolled up his sleeves and took one of the next most important positions in our establishment — in fact, the position which for several years I had feared none but myself could ever fill — the position of directing the purchases. John has filled the position for the greater part of the present year in such a way that I begin to have more faith, perhaps, in the younger ones in general; more faith in Queen Victoria's subjects, and, I trust, more faith in God. May he grant that this union between one of the subjects of the stars and stripes and one of Queen Victoria's domain may be typical of the friendly relations that seem fast growing up between the two nations. Now, then, Bro. Jones of the *C. B. J.*, we extend again to you the right hand of brotherhood, and feel that we have an additional reason to claim relationship.

OUR OWN APIARY.

WEBSTER'S FUMIGATOR, OR SMOKING BEES WITHOUT SMOKE.

THE above fumigator has arrived, and has been tried in "Our Own Apiary." It has the appearance of any ordinary smoker. The barrel, however, is made of zinc, I suppose, to resist the action of the chemical agent used, and is so fastened to the bellows that it can be quickly removed at pleasure. To facilitate handling, the barrel is also fastened a little to one side. In order that you may more clearly understand, I submit a diagram of the Webster fumigator.



WEBSTER'S FUMIGATOR.

At the lower end, you observe, is a cap. The same detached is shown at the upper left-hand corner. To the rim of the cap are soldered four wires, hooked at their ends. In these wires is secured a sponge. This sponge is moistened with 50 or 60 drops of the agent, and on being slipped into the barrel of the fumigator the apiarist is ready for work. Accompanying each smoker is a bottle of the agent, which, I should say, ought to last a season.

WILL THE WEBSTER FUMIGATOR WORK AS SATISFACTORILY AS THE ORDINARY SMOKER?

After having prepared the fumigator as given in the directions, I first tried it on myself, inhaling as much of the odor as I could. Did I experience any disagreeable effects? Not at all, nor was it even unpleasant to me. "Well," said I to the apiarist, "that wouldn't drive even a fly, let alone vicious bees." We selected a cross colony, opened it, and gave then a few whiffs. Yes, it *did* drive them down some, but not like smoke. We then tried the fumigator upon gentle Italians. The effect was the same as before. For vicious bees, the directions say, "Add four or five drops of ammonia to the sponge." On the following day I added the ammonia as directed, and the results were much more satisfactory, and I then opened and examined with it 50 or 60 colonies very successfully. Once or twice, from force of habit, I found my hand jerking back involuntarily when my hand came in contact with the barrel of the fumigator, that member not clearly recognizing the difference betwgen a hot smoker and a cold fumigator. No, it does not have to be handled like hot cakes. It can be picked up without fear of being burned; there is no danger of its setting any thing on fire by contact or sparks; neither does it go out. It is always ready, and requires neither matches nor a dusty litter. I have briefly summed its good features, now let us consider its bad points: The fumigator drives bees to some little extent, and many of the operations connected with bees are assisted by it; but for real conquering and quickness of effect, smoke is far superior. Why? Because smoke is much more severe, and one good puff from the Clark, to my notion, is equal to half a dozen whiffs from the fumigator. The odor from the latter is not pungent enough, even with the ammonia, and *I* did not succeed in making it conquer vicious bees. I recollect in opening one hive of hybrids I had to lay aside my fumigator and bring to bear the smoker. I need hardly say that two or three puffs of the latter made the little rascals succumb. Again, the agent used in the fumigator is a liquid of the consistency of thin syrup, and is very "sticky stuff." Of course, I got my fingers all daubed, and to get it off seemed to baffle even soap and water. Now, I have found from my observation that *not* all men are neat; and if my memory serves me rightly, Mrs. Root, in my hearing, has expressed a similar opinion. I conclude, therefore, in the light of this fact, that *we* must have nothing sticky about a smoker.

THE ODOR FROM THE FUMIGATOR.

There is a very strong odor about the agent used in the fumigator (not pungent, mind you), and the scent has a way of clinging to the clothing, like tobacco from a smoking-car. During one forenoon that I used the fumigator, my clothing had acquired this scent, which smells, as nearly as I can describe, like carbolic acid and tar, of which, indeed, I believe it is made. Yes, my clothing, hives, and, I was about to say, that portion of the apiary where I worked, smelled of that stuff. It so thoroughly destroyed my sense of smell for foul brood, that, in the afternoon, I used the Clark. When I arrived home that noon, Mrs. Root exclaimed, "Why, where have you been? you smell of creosote." Yes, it is true, my clothing did carry the odor of tar and carbolic acid, though I would say that was not at all offensive.

Now, I have endeavored to state candidly the good and bad points with the fumigator invented and sold by W. B. Webster, of Workingham, Eng. I can not say that I think it will take the place of smoke as yet, but I think our English friend has taken a stride in the right direction.

FUEL FOR THE CLARK SMOKER.

In another column our friend J. A. Green tells what and how he prepares fuel for smokers. I see he uses successfully planer shavings in the Clark smoker. Our experience has been much more favorable so far with the basswood sawdust, mentioned on page 551. With the latter it is a common thing for us to make the smoker last for half a day without refilling. To do this we prepare the fuel as follows, for since our last report we have learned some new kinks in filling: Invert the smoker (if you are using a Clark) and drop upon the grate some light rotten elm; next drop a lighted match upon this wood;* work the bellows until the rotten wood is all ablaze, and then drop over this a thin layer of finely broken rotten wood. Work the bellows meantime, and fill with basswood sawdust mixed with a few pieces of rotten wood. There, now, just see what a volume of blue smoke you have! When not in use during the half-day or so, the Clark as thus prepared will die down, but not go out; for you know sawdust will smoulder for a great length of time. A few vigorous puffs will quickly develop a large quantity of smoke. With this sawdust smoke I think I should not be afraid to "tackle" the most vicious Eastern bees, without veil or other protection. In fact, neither has the apiarist nor myself when at work in the apiary had occasion, with one or two exceptions this summer, to resort to the veil; but we have smoke, mind you—enough to make you cry.

BEES ROARING ON RED CLOVER.

While working among the bees the other day, I saw that they were bringing in a large quantity of light-colored honey. Tasting it I detected the unmistakable bumble-bee honey flavor, for which we boys used to pay so dearly. So much of this red-clover honey has come in of late that we shall not be obliged to feed nearly the quantity of sugar syrup we had anticipated. Neighbor Chase, who furnishes us such nice comb honey, says that his 50 colonies have gathered 2000 lbs. of this same red-clover honey within the last few days. Our bees have all been roaring, and as hard at work, apparently, as if on white clover. I have marked two of the colonies whose bees have especially distinguished themselves. One was an imported, and the other a daughter of an imported. We propose to breed from these next season, if all goes well.

---

*I think that I should prefer to light the smoker as recommended by J. A. Green; see page 723.

WINTERING, AND HOW WE PROPOSE PUTTING THE BEES UP FOR THIS WINTER.

I will say at the outset, that our colonies will be put into winter quarters, essentially the same as last year; that is, in chaff hives on their summer stands. As red-clover honey has been coming in very freely of late, some colonies will be given natural stores; but a large number will have to be fed granulated-sugar syrup. Having met with good success in outdoor wintering for the past few years, doubtless many of the A B C scholars would be pleased to know that we are still using the plan recommended in the A B C of Bee Culture. In order that I may give more definite information as to some of the minutiæ, I insert below the following letter, which will doubtless cover many of the queries in the minds of the A B C scholars:

> GLEANINGS of Sept. 1st came to hand in due time, and I was in hopes I should see something from you or Ernest, under the head of "Our Own Apiary," as to how you intend to prepare your bees for wintering.
>
> 1. Have you changed any from the rules you gave in the A B C book of two years ago?
> 2. How much opening do you leave at the entrance?
> 3. Do you use the Hill device now?
> 4. When the hive is full of stores and bees, very heavy, do you remove any of the frames and put in chaff division-boards?
> 5. When a hive is rather short of stores, when and how do you feed, and how fast?
>
> When you introduce a queen by hanging the cage with queen and escorts between the combs, do you spread the combs so the bees can pass between the cage and the opposite comb, or do you put the combs tight up to the cage on both sides? Some advise never to use a queen with her own workers or escorts.
>
> If you will give this information I think you will oblige many, as rules coming from the "Boss" of the "Home of the Honey-Bees." J. H. SMITH.
>
> Stowe, Vermont, Sept. 6, 1886.

Your first question I have already answered.

2. With chaff hives we always leave a full-width entrance.

3. We have used, and still purpose to use, the Hill device. We place it over the center of the brood-nest, with the backbone parallel to the frames.

4. I think not, if I understand the condition of the colony you have in mind. We have sometimes had colonies so strong and well supplied with stores that we have given them the full capacity of the brood-chamber. They were placed on eight frames, spaced out so as to fill the lower story. During winter, combs need to be spread a little further apart than at other times. Whether the colony be strong or weak, it should be *crowded* on as few frames as possible. When the cold weather comes, their contracted apartment, if sufficient stores are provided, will be none too small for them. I would say, that most of our colonies are put on from five to six frames, with a division-board on each side.

5. When short of stores we feed sugar, as recommended in the A B C of Bee Culture; namely, 25 lbs. of sugar to a gallon of water. Perhaps the easiest way, when steam is not to be had, is to pour the water at a boiling temperature upon the sugar; then stir vigorously for a short time. Of all the feeders ever invented, we use and prefer the bread-pan feeder, holding about a pint of syrup. To prevent the bees from drowning, the ordinary cheese-cloth is spread over the pan of syrup. This pan is placed directly over the cluster, the enameled cloth or covering being rolled back. At this time of the year we raise the cover and pour in about a pint every evening. If late in the fall, and the colony is short of stores, we use a milk-pan, prepared as above, filled with syrup. We can thus feed from ten to fifteen pounds in an evening.

In regard to introducing a queen, her escorts will, as a rule, occasion no trouble. I think, however, with a valuable queen I would remove the attendant bees before caging her majesty. We space the two combs, between which the queen is caged, a little further apart, so as to permit the bees of the hive to become "acquainted" with her.

ERNEST.

HOW TO WINTER BEES.

Essays by James Heddon, Prof. Cook, G. M. Doolittle, A. E. Manum, G. W. Demaree, J. E. Pond, Jr., J. H. Martin, C. W. Dayton, and P. H. Russell, all will appear in the October number of the American Apiculturist. Send 10c in stamps for copy.
Address AMERICAN APICULTURIST,
18tf Wenham, Mass.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

A BARGAIN IN HONEY-TUMBLERS.

Among the many cheap packages for retailing extracted honey, the ½-lb. and 1-lb. tin-top glass honey-tumblers hold a prominent place. Though not quite as handy to carry as the glass honey-pails, they are much cheaper, and will be preferred by some. We have at last succeeded in obtaining these direct from the manufacturers, and get jobbers' prices instead of buying them from jobbers, as we have had to do in the past. We can thus offer them to you at the following reduced prices:

½-lb., 3c each; 25c for 10; $2.49 per box of 100; $5.25 per bbl. of 250, or $21.00 per 1000.

1-lb., 3c each; 28c per 10; $2.75 per box of 100; $5.20 per bbl. of 200, or $24.00 per 1000.

Orders for 1000 will be filled direct from the factory in Pittsburgh. You will notice that the tumblers are much cheaper in barrels, as a barrel costs us 35c, and a box of half its size costs 50c.

A. I. ROOT, Medina, Ohio.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

My queens are all gone. I have been overrun with orders for black and hybrid queens.
16-17-18 J. A. BUCKLEW, Clarks, Coshocton Co., O.

Good hybrid queens, 25 cts. each. Some 1 year old, some a month or two old.
J. H. JOHNSON, Middaghs, Northamp. Co., Pa.

For sale, 10 hybrid queens, prolific, the bees being about one-eighth dark, or gray, from them; excellent honey-gatherers, easy to handle. Price, one, 40 cents; two or more, 30 cts. apiece.
CHAS. L. HILL, Dennison, Ohio.

SELLING HONEY TOO LOW.

MRS. CHADDOCK'S VIEWS.

MR. HEDDON says, page 694, "I am sorry to read the low prices Mrs. C. tells us she is selling honey for. I think such low prices for comb honey are entirely unnecessary, and would, if long continued, drive us all out of the business. She is selling at a price below the cost of production, according to Mr. Doolittle, and I think his figures are about right." Well, Mrs. Chaddock feels sorry too; she has several dollars' worth of sorrow on hand. I always feel a sort of flustration when the time comes to begin selling honey. I love the almighty dollar, and I want all of them that I can get; and at the same time I have a conscience that is always pricking and prodding me, and telling me that I am trying to sell things for more than they are worth; and the only way that I know of to do is to strike a kind of general average between my conscience and my desires, and then go ahead. He says such low prices are unnecessary. Well, that is so for this year; but it is not so every year. If there is a big honey-yield, and half the farmers have a little honey to sell, then low prices are a *necessity* to *me*. I am not going to ship a pound of honey if I can help it. I do not want the bother of it, nor the *loss;* and if I can, by any thing short of a miracle, tell what honey ought to sell for here, I intend to sell for that.

Last spring opened up with a grand flourish. Everybody's bees wintered well, and there was honey in the willows and maples, the apple-blossoms, plant lice, and raspberries. The bees bred right up to the white-clover harvest, and were the strongest that I ever saw them so early. The white-clover yield was a princely one, and, right in the middle of it, I began selling honey. In riding about the county I took pains to inquire about other people's bees, and they were all in good condition. Then I read the honey markets as given in the *American Bee Journal* and GLEANINGS. Chicago market, for June 9th and 16th, was 14 to 15 cts., and *selling slowly*. St. Louis market for the same dates read, "Choice comb, 10 to 12 cents; extra fancy, of bright color, and in No. 1 packages, ¼ advance on above prices." I looked at the matter from all directions. I knew that sugar was selling at five cents, and butter at six; eggs at seven, and strawberries that I used always to sell at 40 and 50 cts. were selling at 20 cts. right along; and I could buy just as good lawn for 7 cts. as we paid 12½ for ten years ago; and taking all things together with the big honey-yield that we were *going* to have, I set the price at 10 and 12½. The *cost* of producing a commodity does not fix the price at which it *must* sell. A great plenty of any thing brings down the price. But the great plenty did not come. The white clover yielded splendidly; but when it was gone, every thing stopped short. Then I stopped selling at 10 cts., and I now sell only at retail. I am going to let the farmers supply the town markets with their five-cent comb honey for awhile. I'm awfully scared, I tell you. May be I've injured the honey-business all over the United States and Europe. I promise Mr. Heddon never to do the like again unless I do not know any better.

Vermont, Ill. MAHALA B. CHADDOCK.

You are touching quite an important matter, my good friend. Few things require more wisdom in business than in deciding just when to drop prices. The merchant who purchases goods that are not perishable has no trouble at all in deciding that, if he buys an article for 8 or 9 cts., and sells it for 10, he is all right; but the bee-keeper or the farmer who produces his goods by tilling the soil rarely knows exactly what they cost, and it would not matter much if he did. Every thing is so uncertain in his business that it is his duty to find the best market he can. If he can get more money for his produce by going to a large city—that is, after all expenses are paid—by all means let him do so; or if he can get more money by putting up his crop in small neat packages, and taking it fresh to people's homes, by all means do that way; but when he is satisfied people won't pay what he thinks he ought to have for his product, then he must either improve the appearance and style of his packages, or drop the price. I would not drop the price until it seemed to be the last resort. Raise the quality if possible, so as to keep the price uniform. Where the prices have been established, and the goods are going off freely, I would prefer to buy out some small producer rather than let him injure the market; and sometimes it pays better to buy out such producer, even if you can't sell the stuff for what you paid for it. But this would refer to small lots, of course. If the farmers round you have small lots of honey that they seem disposed to run off at 5 cts. because they don't care to bother with it, I would try to find out about it beforehand, and take it off from their hands. Perhaps you may be obliged to sell it for 5 cts. per lb. yourself; but it will hurt your trade very much less in that way, because you can explain to your customers the difference in quality, style of package, etc.

CHEAPEST OFFER EVER MADE.

In order to introduce my stock more extensively I will sell pedigreed Poland-China pigs, from prize-winning stock, at only 6 cts. per pound, spring pigs. Small pigs, not akin, $5.00 per pair. Sent at reduced rates by American Express. Safe arrival and entire satisfaction in every case guaranteed. Full colonies of Italian bees in A. I. Root's Simplicity hive, $4.50. Address **N. A. KNAPP,**
18d Rochester, Lorain Co., Ohio.

LARGEST BEE-HIVE AND SECTION FACTORY IN THE WORLD.

GREAT REDUCTION!

ON THE ONE HAND

It treats pleasingly of flowers, pot-plants in the window and under glass; fine lawns, trees, shrubs, and the beautiful of Gardening; on the other, taking up the matter of better fruit and vegetables for our tables every day, and the largest profit for market-growers in all branches of Horticulture. We are speaking of our journal,

POPULAR GARDENING, AND THE FRUIT RECORDER.

It is a most useful and readable paper. Its style is plain, sensible, and practical; no waste of words, no long dry articles. Finer engravings and printing than its columns show can nowhere be met.

ON TRIAL 3 MONTHS 15 CTS.

This paper every American family should see, so we will send a sample copy to any address for 6 cents.

Popular Gardening Pub. Co., Buffalo, N. Y.

BEE-KEEPER'S GUIDE;

Or, MANUAL OF THE APIARY.

13,000 SOLD SINCE 1876.

14th THOUSAND JUST OUT!

10th THOUSAND SOLD IN JUST FOUR MONTHS!

5000 Sold Since May, 1883.

More than 50 pages, and more than 50 fine illustrations were added in the 8th edition. The whole work has been thoroughly revised, and contains the very latest in respect to bee-keeping. It is certainly the fullest and most scientific work treating of bees in the World. Price, by mail, **$1.25**. Liberal discount to dealers and to clubs.

DADANT'S FOUNDATION FACTORY, Wholesale and retail. See advertisement in another column. 3btfd

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or $2.00 per annum, when given once a month, or $4.00 per year if given in *every* issue.

$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or $2.00 per year.

Those whose names appear below agree to furnish Italian queens for $1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable. Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for $1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

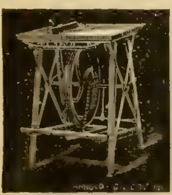
Barnes' Foot-Power Machinery.



Read what J. I. PARENT, of CHARLTON, N. Y., says — "We cut with one of your Combined Machines last winter 50 chaff hives with 7 inch cap, 100 honey racks, 500 broad frames, 2,000 honey-boxes and a great deal of other work. This winter we have double the amount of bee hives, etc., to make and we expect to do it all with this Saw. I will do all you say it will." Catalogue and Price List Free. Address W. F. & JOHN BARNES, 68 Ruby St., Rockford, Ill.

When more convenient, orders for Barnes' Foot-Power Machinery may be sent to me. A. I. ROOT.
23tfd

IN order to reduce my stock I will sell 20 colonies of hybrid bees at $5.00. They are in Simplicity hives on wired frames, have plenty of stores for winter, and before shipping will be packed ready for winter, including 2 chaff cushions and Hill's device. 19d GUSTAVE GROSS, Greenville, Bond Co., Ill.

HONEY COLUMN.

CITY MARKETS.

NEW YORK.—*Honey*.—New comb honey is coming in quite lively, and we find it to be of very nice quality. We quote:

Fancy white, 1-lb. sections,	14@16
" " 2-lb. "	12@14
Fair " 1-lb. "	12@14
" " 2-lb. "	10@12
Buckwheat 1-lb. "	11@12
" 2 lb. "	9@10
California extracted	5@5½

We find a good demand for honey, and expect to handle large quantities.

Sept. 22, 1886. THURBER, WHYLAND & CO.,
Read and Hudson Sts., New York.

KANSAS CITY.—*Honey*.—The market is good for all grades, and sales are large, while the supply is the same. Prices are unchanged.

White clover, 1-lb. sections	13@14
" " 2-lb. "	11@12
Dark 1-lb. "	11@12
" 2-lb. "	9@10
Light ½-lb. "	14@15
Extracted, white clover	6@7
" dark	4@5
" white sage	5@5½
Beeswax,	20@22

Sept. 24, 1886. CLEMONS, CLOON & CO.,
Cor. 4th and Walnut St's, Kansas City, Mo.

ST. LOUIS.—*Honey*.—Honey is still dull. California is offering white sage, extracted, put up in two 5-gallon cans in case, at $4.85, laid down here in carload lots. Amber, same packages, $4 50. For white clover comb sections we are getting 11@12½c½; extracted, in cans, lots, 5@6c; single cans, 6@7c. Southern honey, in bbls, 3½@4c as to quality. There is a good demand for comb honey. *Beeswax*, 21@25c. WESTCOTT & HALL,
Sept. 22, 1886. 108 and 110 Market Street.

DETROIT.—*Honey*.—Honey is being shipped in more freely of late, and prices are lower. All sizes larger than one pound are selling at 12 cts. Pound size, 12½@13c for best white. *Beeswax*, 23c.
Sept. 23, 1886. M. H. HUNT, Bell Branch, Mich.

CHICAGO.—*Honey*.—There is more demand for comb honey, and prices are firmer—12½@13c being asked for best grades of white comb honey; extracted, 5@7c. *Beeswax*, 23c. R. A. BURNETT,
Sept. 21, 1886. 161 So. Water St., Chicago, Ill.

CLEVELAND.—*Honey*.—The market has not improved of late, but prices are steady at 14 cts. for best white 1-lb. unglassed sections; 12 cts. for 2 lbs., best white; 8@9c for 2 lbs. and 1 lb. old. Extracted, 6@7c. *Beeswax*, 25c. A. C. KENDEL,
Sept. 22, 1886. 115 Ontario St., Cleveland, O.

BOSTON.—*Honey*.—We note no change in prices, but an improved demand. BLAKE & RIPLEY,
Sept. 23, 1886. 57 Chatham St., Boston, Mass.

FOR SALE.—13,000 lbs. clover honey, first class, and well ripened before extracting. Delivered at depot in barrel lots at 7 cts. H. W. FUNK,
Box 1156. Bloomington, Ill.

FOR SALE.—3000 lbs. extracted honey, in ten-gallon kegs, 117 lbs. net; 7 cts. for white clover; 6½ for raspberry. M. ISBELL, Norwich, N. Y.

CHEAP HONEY.—I have about 3500 lbs. of honey in nice 22 gallon kegs. It is dark, but very thick, and is splendid bee-feed, or good for factory-men. I have to move soon, and must sell it. You may have it for 3 cts. per pound, by the keg of 250 lbs., at depot here. M. J. HARRIS,
Clay City, Clay Co., Ill.

Foundation-Mill For Sale.

One ten-inch Root comb-mill, second hand. The mill has, however, been completely fitted up, painted, and varnished, and is, to all appearances, both in looks and quality of work, equal to a new one. Price $15.00. The list price of a new mill of this kind is $20.00. **A. I. ROOT, Medina, O.**

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I still have a goodly number of black and hybrid queens for sale. Black, 18 cts.; hybrid, 25 cts.
W. G. HAYEN, Pleasant Mound, Ill.

Do not by any means insert hybrid-queen advertisement again. I am returning money evey day, but have to withhold some, from the fact that I can't make out where in the U. S. to return it, no definite address accompanying it. C. L. HILL.
Dennison, O., Sept. 24, 1886.

4 H.-P. ENGINE FOR SALE.

A Bargain for the man who is in need of a First-Class Engine and Boiler.

This is one of B. W. Payne & Son's Eureka engines, the same that we advertise in our catalogue. It has run 3 months since it was new; has had a 10-foot galvanized-iron smoke-stack added, and is in perfect running order. The man who is holding it had to put in a larger one to meet the demands of his trade. The price of a new engine and boiler complete, no stack, is $275.00; but to make a quick sale we will sell this one with the stack for $225.00, free on board cars at Higginsville, Mo.

A. I. ROOT, Medina, Ohio.

THREE untested Italian queens at 50 cents each.
M. ISBELL, Norwich, N. Y.

CONVENTION NOTICES.

The Sheboygan Co. Bee-Keepers' Association will hold its next meeting at Chandler's Hall, at the village of Sheboygan Falls, on Saturday, Oct. 16, at 10 A. M. MRS. H. HILLS.
Sheboygan Falls, Wis.

The Southern Ill. Bee-Keepers' Association will hold its next meeting at Benton, Franklin Co., Ill., Thursday, Oct. 21, 1886, at 10 A. M. F. H. KENNEDY, Sec.

The annual meeting of the Western Bee-keepers' Association will be held in Pythian Hall, corner of Main and 11th Streets, Kansas City, Mo., Oct. 27, 28, 29, 1886. P. BALDWIN, Sec.

The Illinois Central Bee-keepers' Association will hold its next meeting at Mt. Sterling, Ill., on Tuesday and Wednesday, Oct. 19 and 20. J. M. HAMBAUGH, Sec.

The 4th annual meeting of the Progressive Bee-Keepers' Association will be held in the Town Hall at Bainbridge Center, O., on Thursday, Oct. 7, 1886. Parties wishing conveyance from Geauga Lake Station, 3 miles distant, on the N. Y., P. & O. R. R., will please notify me so that arrangements can be made for the same. All interested are invited to come and bring their lunch-basket. MISS DEMA BENNETT, Sec.
Bedford, Cuyahoga Co., O.

There will be a bee-keepers' convention in K. of P. Hall, No. 1158 Main St., north of 12 St., Wheeling, W. Va., on Oct. 15, 1886. Bring samples of honey and other things. HENRY LEWEDAG.
Wheeling, W. Va.

The semi-annual meeting of the Central Michigan Bee Keepers' Association will convene in Pioneer Hall, at the Capitol Building, in Lansing, on the third Tuesday of October, at 10 o'clock A. M. J. ASHWORTH, Pres.
Lansing, Mich.

THE NORTH AMERICAN BEE-KEEPERS' SOCIETY.

The society will hold its 17th annual convention, Oct. 12, 13, and 14, 1886, at Indianapolis, Ind.

The meeting will be held in Pfaffin's Music Hall, 82 and 84 North Pennsylvania St., one of the most pleasantly situated halls in the city. Good ventilation and plenty of light.

The society headquarters will be at the Occidental Hotel, corner of Washington and Illinois Sts., in the heart of the city, and but a short distance from the hall. The regular rates at this hotel are $3.00 a day. Special rates for those in attendance at the convention will be $1.50 per day.

The North-Western Bee-Keepers' Society, The Indiana State, The Eastern Indiana, with various county and joint societies, will meet in union with the N. A., making it one of the most formidable meetings of bee-keepers ever held in this country. Every thing possible will be done to make the meeting pleasant and entertaining. A cordial invitation is extended to all.

GLEANINGS IN BEE CULTURE.

DEVOTED TO BEES HONEY & HOME INTERESTS.

Vol. XIV. OCT. 1, 1886. No. 19.

TERMS: $1.00 PER ANNUM, IN ADVANCE; 2 Copies for $1.90; 3 for $2.75; 5 for $4.00. 10 or more, 75 cts. each. Single Number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent TO ONE POSTOFFICE.

Established in 1873.
PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

EXPELLING BEES FROM INCORPORATED TOWNS.

PROF. COOK CONSIDERS THE MATTER.

OUR city council is about passing an ordinance excluding all bees from the corporation. We have perhaps 15 persons who keep bees, and they do not have over 100 stands, all told; but owing to ignorance and prejudice they are about to banish all bees. We do not want any trouble, and shall do all we can to keep peace; but if worse should come to worst, can you give us any light as to the legal points in the case?

Barry, Ill., Sept. 14, 1886. H. C. FIRST.

The above was forwarded to Prof. Cook, requesting that he would give us his opinion, and especially that he would advise in regard to the matter. Below is his reply:

This matter of antagonism between bee-keepers and those of other occupations is surely becoming a serious one. Truly, if bees are a nuisance—and on no other ground can they be forced from village or city—it is strange, passing strange, that we—aye, the world—had not found it out before.

We now have nearly 50 colonies of bees here at the college, and, as you know, Mr. Editor, we are a little hamlet, and these bees are within three rods of Dr. Beal's barn, and only two or three rods further from his house; yet I have never heard Dr. Beal complain a word. Several people in Lansing have bees, and I have never heard a word of complaint. I know of a city in Michigan where two or three quite large apiaries have been kept right within the corporation, and yet no complaint, so far as I know, has been made.

We all know, that, in spring, bees may soil clothes hung near by an apiary, and we know that bees may become very cross in autumn, and may thus greatly disturb those who may either by chance or necessity come near the bee-yard. We also know, that, in times when no honey is being gathered from the flowers, bees may attack fruit or exposed sweets in houses and stores, and thus become sometimes almost an insufferable annoyance, especially to those who are unused to bees, and so have a terrible dread—and just as terrible, even if groundless—of being stung.

I do not believe any town council will unite against the bee-interest unless there is some cause. Almost all our people respect any honest, legitimate industry; and surely ours must be respected, not only from its merits but from its very age.

THE BEE-KEEPER'S DUTY.

Now it occurs to me, that each bee-keeper ought to reduce these disturbing elements to the very lowest minimum. In spring, why not shut the bees in on wash-days, if a near neighbor is to be annoyed? I know wash-day is hard enough for my wife, even at best, and it would be a sore vexation to her and me (for what hurts the "gude wife" hurts me more), if that ring of immaculate white which adorns our clothes-reel each Monday were to be flecked with the dirty yellow which often marks the first flight of bees. How easy to prevent this on the part of the bee-keeper! Duty demands that neglect in this shall never break the friendship of neighbors.

But how about the troubles in fall? We all know, that, if we work late in the season with hybrids, or bees disposed to be cross, in the usual way, when there is no honey to gather, especially if it is cold, we incite such anger that the bees may not be approached, even from quite a distance, without danger of stings. In such cases, if we have near neighbors we must not work with the bees; or if necessity compels such work, *never work without a bee-tent.* Then we do not cause the bees to become irascible; we get no stings ourselves when at work, and we run much less danger of inciting the bees to rob. Just this one precaution may save a neighborhood quarrel. If in September we find our bees are greatly troubling our neighbor with his fruit, can't we shut the bees up, put them in the cellar, or even remove them a mile or two, rather than awaken the displeasure of our neighbors?

Again, if we find our neighbors are troubled, why not go to them with a heart full of love and our hands full of nice honey, and say we regret this annoyance, and talk over the matter, asking for forbearance, and promising all possible caution? Such a course will win our neighbor, and what more glorious than that? When the grand apostle Paul said, "As much as lieth in you, live peaceably with all men," he was simply urging against quarrels, for a quarrel is very difficult when one of the parties has only love in his heart. Next to a perfectly harmonious home is a perfectly united neighborhood. Let each of us bee-keepers do our part to secure just such a one at our place, and I believe there will be few occasions to invoke the aid of law, and few to call for the aid of "the Union."

THE LAW, AND BEE-KEEPERS' UNION.

No doubt some have feared that the "Union" might become a sort of heartless monopoly, a huge sort of "boycotter," whose tendency would be to stir up broils. Very likely there will arise cases like that in Wisconsin, when, with even the greatest care, litigation can not be avoided. In places like California, where the fruit-interest is of such magnitude, it may be almost impossible to avoid prosecution at the hands of the law. Good men *may* possibly feel that bees and bee-keepers are really a nuisance, and call upon legal authorities to settle the matter. In all such cases the case of each bee-keeper is that of all, and I see no justice in making the one unfortunate bear all of what might have come to any one of us; hence I believe in the "Union," and feel glad to support it. But I also feel that the "Union" must be very wary. It *must see* that in *all cases* the bee-keeper has done *all in his power* to preserve peace, before it lend its aid. If a bee-keeper is "cranky" and irritable, and tries to provoke, rather than allay strife, then he should be forced to bear his own burdens. It is to be hoped that the "Union" will, in every case, fully investigate, and never come to the rescue unless it find that the bee-keeper has done all in his power to make all satisfactory without appeal to law. What a grand lesson our "Alabama-claims arbitration" gave to the world! Let us all profit by it. If, however, we find that circumstances make it imperative that the law settle some of the equities which bear upon bees and their relations to fruit, then let us all help bear the burden; for we all share the benefits of a verdict which we need not fear.

A. J. COOK.

Agricultural College, Mich., Sept. 22, 1886.

Friend Cook, I knew we should get something good and substantial from you in regard to this matter. I had not thought of shutting the bees in their hives at the time they soil clothes, but I think it can be done with plenty of wire cloth, without harming the bees; and after the bee-keeper has done that, it may transpire that the bees that do the mischief come from somewhere else. This happened at one time when we had our troubles with the "cider-mill man." We watched the Italians that were working on the sweet cider, and then showed him that the greater part of them went off in another direction, and obliged him to admit it. A great many times innocent bee-men are blamed, when the bees that are doing the mischief come from the woods or from some other apiary. If it is found to be impracticable to shut up the hives, I would move the bees away temporarily. I am sure this would be better in the end than lawsuits and hard feelings.—In regard to the Bee-keepers' Union, I hope and pray that those who have the matter in charge may be very careful that it never show its power unless it is absolutely necessary.—Now in reply to our good friend F., who opens this article, can't he profit by some of Prof. Cook's advice, and so present the matter to the council that the banishment may be unnecessary? Let us all remember Paul's wonderful text, "If meat make my brother to offend, I will eat no flesh while the world standeth."

THE NORTH-AMERICAN CONVENTION.

IS IT THE DUTY OF BEE-KEEPERS TO MAKE SOME EXERTION TO ATTEND IT?

ERE another number of GLEANINGS is printed, the North-American Bee-keepers' Association, the Northwestern Bee-Keepers' Association, the Indiana State Bee-Keepers' Association, and I don't know how many other district and county associations, will have met in a grand convention at Indianapolis. Association is a great thing; it fosters, encourages, brings out, and makes known individual efforts, plans, and inventions; not only this, but the friction of mind against mind seems to bring about a polish and sharpness that can be secured in no other manner. We think better of our fellows by coming in contact with them. The corners are thereby knocked off. We learn to measure *ourselves;* to see our faults and failings; possibly to discover some hidden excellencies that we knew not before that we possessed.

The social feature of these meetings is the grandest of all; it does one good to grasp the hand of an old friend, look in his face, and listen to his words, or to meet some one whose writings we have followed for years, and whom we have often wished to see. Then there are the little chats in by-places, at the table, and the long-continued, half-confidential talks indulged in long after Morpheus has beckoned with outstretched arms. But why say more? Those who have attended a good bee-convention know exactly what a "flow of soul" there is, and that all go home greatly encouraged, feeling more than ever that they can and *will* make a success of bee-keeping.

I think that we as a people go too little for *pleasure* or *recreation.* Where had a bee-keeper rather go, even for *pleasure*, than to a grand *national* convention of bee-keepers? I have met many of my brother bee-keepers at conventions, but I hope to meet still more of them at the coming meeting at Indianapolis.

By the way, it may be cheaper for many to go via Chicago, as we can secure *very* low excursion rates to that city, and reduced rates from Chicago to Indianapolis. I *think* I shall go that way myself. There is only one objection to my going via Chicago; and that is, that I can buy an excursion ticket upon Tuesday *only*, hence I can not reach Indianapolis until Wednesday morning.

Rogersville, Mich. W. Z. HUTCHINSON.

Friend H., I believe I entirely agree with you here in regard to the benefit of conventions. I suppose each bee-keeper, however, knows best whether he can afford it or not. So far as I am concerned, I feel now that I have no right to be absent, and I expect to attend every *national* convention held, so long as I live and God gives me health and means to be on hand.

CAMPANEA, OR BELLFLOWER.

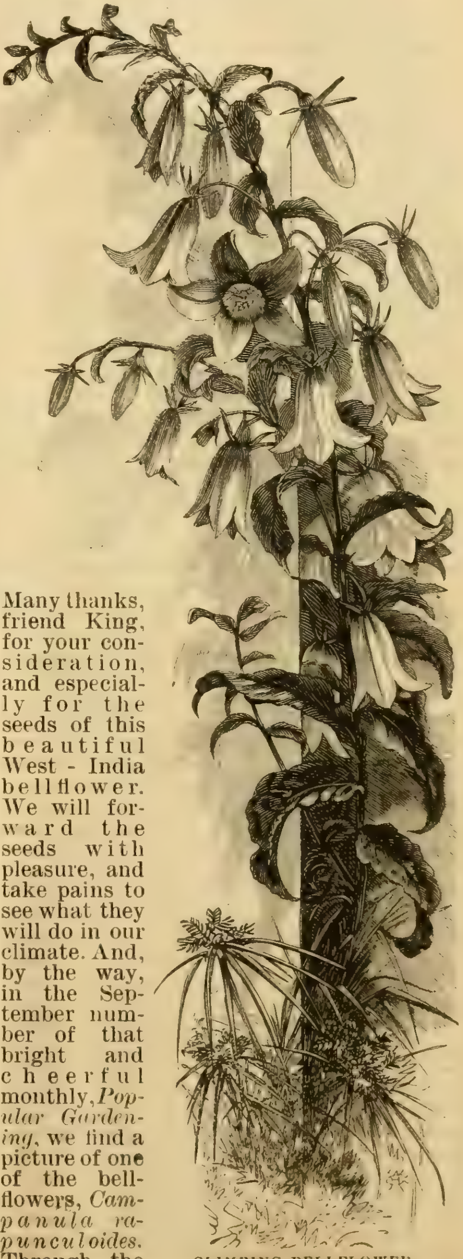
THE GREAT HONEY-PLANT OF THE WEST INDIES.

THE campanea (better known as bellflower) is indigenous to all the West India Islands. There are at least four varieties, two of which are known to yield honey. One of these blooms from about the middle of September till March, but yields very moderately. The other blooms from November till March, and is at its best from December to about February 15th, when it gradually declines and finally ceases altogether by the 1st of March. This last variety is far more numerous than all the others combined, covering the hedges, small branching trees, and bushes, throughout the length and breadth of Cuba, scenting the air with its sweet and delicate perfume — not unlike that of the pink during the period of its bloom.

In describing the appearance of this trailing vine in full bloom, friend Osborn aptly compares the sight to "long windrows of drifted snow seen at a distance." When in the vicinity of large apiaries, the volume of sound occasioned by the mingled hum of millions of contented bees and other insects, all busy in gathering the delicious nectar, reminds one of the music of ocean waves breaking on a distant rock-bound coast. Strike from the list of honey-producing flora this queen of flowers, and you diminish by more than one-half the entire honey production of the West Indies.

In appearance, bellflower much resembles the morning-glory, the bloom being about the same size and shape, but perfectly circular and more flaring. In color it is white, except about one-fourth of its lower and inner concave surface, which is a dark purplish yellow. The nectar is as white as that obtained from the basswood — very thick, averaging 12 lbs. to the gallon. It has a delicate aroma, and is the most delicious and palatable of any variety of honey we ever tasted, and is destitute of that "stinging" sensation in the throat, so common to most of the honey produced in this country, particularly that gathered from white clover. As the Cuban *winters* — when campanea is in full bloom — are not unlike our *summers*, it occurred to me that this plant, by the peculiar process known to botanists, might, in the course of time, be so acclimated as to prove a boon to our honey-producers. With this end in view I send you some of the seeds of this best variety, gathered by myself, requesting you to send a little to friends Newman and Prof. Cook, and to any others you think possess the patience and facilities for giving the plant a fair chance. Of course, you will be expected to be chairman of that "committee," and be the chief experimenter, reporting progress from time to time through the columns of GLEANINGS. A. J. KING.

New York, N. Y., Sept., 1886.



CLIMBING BELLFLOWER.

Many thanks, friend King, for your consideration, and especially for the seeds of this beautiful West-India bellflower. We will forward the seeds with pleasure, and take pains to see what they will do in our climate. And, by the way, in the September number of that bright and cheerful monthly, *Popular Gardening*, we find a picture of one of the bellflowers, *Campanula rapunculoides*. Through the kindness of the editors, we are able to give it here. The writer in *Popular Gardening* states that there are 280 distinct species. Roots of this plant can be obtained of Elwanger & Barry, of Rochester, N. Y., and others. It is certainly a very handsome vine; and even should it not yield honey like the one mentioned by friend King, it would not be a very great disappointment to the purchaser. As some varieties of the plant seem to be found in almost every part of the world, it would be nothing strange at all if the honey-producing bellflower could be acclimated, as friend King suggests. We will take good care to plant the seeds at the proper time, and report through GLEANINGS.

WHAT IT COSTS TO PRODUCE A POUND OF HONEY.

CAN THE QUESTION BE ANSWERED SO AS TO APPLY TO ALL LOCALITIES?

I HAVE read with interest what has been said in GLEANINGS with reference to the cost of production of a pound of honey. Mr. Doolittle and Mr. Heddon appear to agree as to the cost of production, while I see it in a far different light. It does not cost the same to produce a pound of honey in Illinois that it does in Vermont, as the cost of living is much cheaper here than there. I bought a large watermelon last evening for five cents; and when I was in Vermont, five years ago, they were sold there by the pound, and many garden vegetables were shipped there and sold at high rates. In Illinois, good corn lands are worth from sixty to sixty-five dollars per acre; and shelled corn at railway stations sold for 28 cents per bushel this summer. Mrs. Chaddock says, "Butter sold in my locality for six cents per pound," and I was there several years since, and bought, late in November, fine gilt-edge butter for ten cents per pound. Farm products are not worth the same all over the United States, and why should honey be?

A German grocery-woman yesterday said to me: "Some farmers brought in honey, and took about what they could get for it; you will never see them around with any more." Peoria has a population of 40,000. Many railroads center here, and bee-keepers think that is the place to sell honey. So they come from every point of the compass, driving many miles in light spring wagons, and could have sold honey faster and for more money, all the way, but they never tried to. They are like the man who went hunting rabbits, and saw plenty of deer, but would not shoot them, for he was not hunting deer but rabbits. They sold their honey for 8, 9, or 10 cents per pound, and took their pay in trade, or in part that way. Dealers say they tried to hold honey at 15 cents, but they could not do it, for many others were selling at 12½ cents. Every groceryman who handles it has a supply, and has bought choice white clover in one-pound sections at 10 cents per pound. We are not pushing our honey on the market, and are selling only to old customers in exchange for needed supplies. It appears to me to be folly to do otherwise; that is, to be paying out money for such things as honey ought to buy.

Mr. Harrison says when honey will not bring 12½ cents per pound, a man had better engage in some other business. If he has ability to produce honey he can make more in some other way. I consider this crop of honey that we now have, to have cost the most of any we have had, for this reason: I was sick during the busy season. I have not put on nor taken off a surplus box. Mr. Harrison has done the work, and his time is worth in the world's market more than mine. I know a bee-keeper who has a wife, two daughters, and a little boy eight years old. They all work in the apiary during the busy season. If he worked at his trade, which is shoemaking, the rest of the family would be consumers, when now they are producers. One of the brightest features in bee-keeping is this: It can be done at home, and members of the family can be helpers who could not earn a dollar in any other way. What can Mrs. Chaddock or Mrs. Axtell do at home on a farm, that will pay any better?

Peoria, Ill., Sept., 1886. MRS. L. HARRISON.

I think your point is a good one, Mrs. H.; and is it not also true that one can produce honey at a less price than another can? Friend Terry estimates that he can raise potatoes at a cost of 20 cts. per bushel, and allow reasonable pay to all hands employed in the work, and six per cent interest on the value of the land. He says, however, he thinks that the way many farmers work, and the number of bushels they get per acre, makes them cost fully 40 cts. In your closing remarks you touch on another point. Many people can keep bees and produce honey, who can not very well do much of any thing else. One of our agricultural papers said the same thing in regard to raising wheat. Suppose a farmer decides that he can not raise wheat for 70 cts. per bushel without losing money, what then shall he do—let his team stand in the stable, let the land lie idle, and sit around and talk over the discouragements of farm life? Why, it seems to me he had better keep at work—keep his teams at work and use his land, even if he gets but 50 cts. a bushel. Of course, he might raise something else in place of the wheat; but with bee-keepers, as you very fairly put it, are there not a good many who can not very well do much of any thing else? The remedy for breaking down prices, as it seems to me, is for some one to establish himself as a buyer, just as we have wheat-buyers and wool-buyers. Everybody in Medina knows that I am a honey-buyer; and if there is any honey to be "fooled" away, it generally gets into my hands.

EMPTY BROOD-NESTS.

FORMING NUCLEI, A LA DOOLITTLE.

IN GLEANINGS for July 15, page 563, in the closing of friend Hutchinson's letter he said: "Just stop and think a moment, friend R., and see if you can't "catch on." Now, friend R., it has been easy for me to "catch on" to the honey part, but nice worker-comb I can't "catch on" to. To try friend H.'s plan, I hived, about the first of June, 5 first swarms in as many hives having the brood-chambers contracted by division-boards, giving each swarm 5 frames having fdn. starters about one inch wide. Upon 3 of those colonies I placed crates whose sections were filled with fdn.; upon the other two I placed the queen-excluding boards, and upper stories filled with empty combs. From those colonies I got almost every drop of honey stored above, leaving the brood-chambers destitute of honey, but filled with brood, and that the finest lot of drone-brood you ever saw; but it was drones that I did not want, as they were not choice queens. I give the result of each individual colony:

Hive No. 1 contained a queen one year old; one frame was filled with worker-comb; one was two-thirds full of worker-comb, and the rest was drone. The other three frames were full of drone-comb from top to bottom.

No. 2 had no frame that was filled with all worker-comb; about worker-comb enough to fill three frames, queen one year old.

No. 3 contained a queen two years old, and not worker-comb enough to fill two frames; two frames were entirely full of drone-comb.

Nos. 4 and 5 were run for extracted honey.

No. 4, queen one year old; 2 frames full of worker-comb; one, half full of worker-comb and one a third full; two frames of combs, full of drone-comb.

No. 5, the queen was two years old; about worker-comb enough to fill three frames; no frame entirely full of drone-comb; sections were placed upon those hives before the bees were run in. Extracting-supers were put on as soon as the bees were run in.

DOOLITTLE'S PLAN OF FORMING NUCLEI.

This plan, from the pen of friend Doolittle, has been worth more to me than GLEANINGS has cost me in the last five years. I never take any risk in placing cells in queenless colonies. I place cells in the queen-nursery, and when queens are 3, 4, or 5 days old I make nuclei for them and introduce without the loss of a single queen. When I want to introduce a queen to a colony of bees, I take a nucleus from the old colony, introduce my queen, and when she has commenced laying I make the old colony queenless; and at the end of 24 or 48 hours I unite the two in a new hive. Yes, friend Doolittle, it is easy to tell when they fairly "cry" for and will accept any kind of a queen.

J. A. BUCKLEW.

Clarks, Coshocton Co., O., Aug. 5, 1886.

TEASEL AS A HONEY-PLANT.

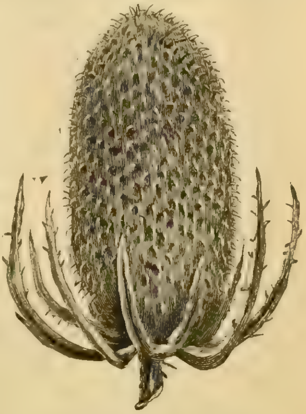
A REPORT FROM ONE WHO RAISES TEASELS AND KEEPS BEES AS A BUSINESS.

FRIEND ROOT:—Why do you allow such an engraving of a teasel to appear as you have in your A B C, and as has appeared in the *A. B. J.* I have been in the teasel-business for the last ten years, and now have twenty acres occupied with them. As you all know, I am a bee-keeper too, and it makes me just crawl to see such a botch of a job come from one of our leading periodicals. Inclosed find a medium teasel, ready for market. If you will have an engraving made right, I will gladly send a specimen. I am just harvesting my crop, and you will see some are not yet dry. I claim to be the only bee-keeper and teasel-grower to any extent. I tried one stock this season, and it made 48 lbs. of exclusively teasel honey.

C. M. GOODSPEED.

Thorn Hill, Onondaga Co., N. Y.

Good friend G., we are exceedingly obliged to you. The reason why you are so disgusted with the cut in the A B C book is, I presume, because it was made from one of the wild teasels growing in our vicinity. At the time it was made, I was in the habit of having engravings drawn from real specimens as far as possible, and I did not know there was so much difference in the appearance of the two varieties, especially as I saw the bees working on the wild ones. We now take pleasure in submitting to our readers a cut made from one of the heads you sent us.



HONEY-BEARING TEASEL.
Dipsacus fullonum.

We are especially glad of the report you make, of 48 lbs. from a single colony. If this could be depended on every year, I presume some more of us could well afford to have 20 acres. We should be very glad indeed of full particulars in regard to the cultivation of teasel, marketing the crop, etc.; and as you seem to be especially well prepared to give us the facts, we will gladly pay you for such an article. Very likely, however, the vicinity of large woolen-mills would be the most advisable locality for starting an apiary in connection with a teasel and honey farm.

FOUL BROOD.

SOMETHING FURTHER IN REGARD TO THE HOYLE THEORY OF THE DISEASE.

FRIEND ROOT:—I thank you for your remarks on a recent article of mine on this subject, which I regard as very favorable, considering the brief period you had in which to view the question from my standpoint. The more you look at the subject from my position, the nearer will our ideas about it agree. I may be wrong in some particulars; but, I hold, I am correct in the main; and if any think that, after viewing the subject from my present position fourteen months, I am now offering a theory that is easily broken down, why, they are welcome to try their hand in pulling it to pieces. I do not say that bacteria has nothing to do with the disease, but that it attacks only the larvæ when the larvæ are weakened, or ill from some other cause. In my first article on this subject I mentioned two causes from which larvæ become ill. I will now tell you of a third, which is, insufficient attention from the bees. It is nothing serious, though, if one does not mistake the cause, and kill a valuable queen. This state is brought on by the bees trying to care for more larvæ than they are able to care for. And sometimes it *seems* to be caused by stinginess in the bees during a honey-dearth.

It is my firm belief, that this same bacteria is everywhere, and that it wants only a favorable opportunity to break out in any apiary. Friend R., if the people were to stick to the old idea about this disease, you would be sure to suffer, and unjustly too. How? Why, in this way: Say you effectually rid your apiary of the disease, and sold some bees to a party who had never had or seen any of the disease in his locality; and in that year there is a honey-dearth, and only a little inferior honey-dew is to be had in his neighborhood, in which case he is apt to have the disease, as anybody is with such a honey resource; nevertheless, he would blame you for it, and so would all others who hold a like view of the disease.

I can not afford the time it takes to write up this subject, and I would not have commenced it yet awhile, but I thought it might benefit you, and no doubt it would if you would only believe in it. There is one thing of which I am certain; and that is, that it will benefit you in the future.

Mobile, Ala., Sept. 22, 1886. GEO. H. HOYLE.

Friend H., although I can not entirely agree with you in regard to the origin of this disease, it occurs to me to mention a few facts favoring your position. You know we have for some time been searching to find whether blight and similar troubles in the vegetable world are caused by disease or by an insect-enemy. Well, for some time it has been supposed that blight in celery was produced by an insect, because this insect was found on the plant when the blight appeared; but Mr. Rawson, in his recent work on celery culture, says he can not agree that the insect is the cause. He says the cause is mainly want of water, as the celery is a water-plant, and many others have decided the same way. The blight may, however, be produced by an *excess* of water, and the cause he gives is, lack of vitality in the plant caused by either extreme—too much or too little water. Now, the reason why certain parties think the insect is the cause, is because it is a fact that the insect makes its appearance about as soon as the blight starts; but he says the insect simply follows, and has nothing to do with the origin of the trouble. You know this has been decided to be the case with the moth-miller; and even now, where modern bee culture has not shed its light, there are people to be found who think that the moth killed their bees. Peter Henderson recommends, as the best remedy against the attack of all insect enemies, making the plant push ahead with such vigor that it lives in spite of the insects. Who has not noticed how the bugs will pitch into a *feeble* squash-vine, letting the rank, strong-growing plants almost alone? And so it is with most of the insect-enemies of the vegetable kingdom. Now, then, can it be true that the spores of this disease, foul brood, get a foothold only where the brood is in a favorable state, from some of the causes you mention? In that case, powerful colonies would be found less affected than the others, would they not? But, if I am correct, facts do not corroborate this. Am I not right? It is possible, however, that all the colonies in the apiary, strong and weak alike, gather something that is injurious to the brood, or enfeebles it, and, as a consequence, foul brood gets a foothold; but the facts, so far as I am acquainted with the disease, are, that certain localities are absolutely free from it; but when it once gets established in these localities, it seems to be hanging about almost ever afterward.

WHAT AILS THE BEES?

IS IT A POISON, OR IS IT A DISEASE?

FRIEND ROOT:—With your permission I will tell my tale of woe. I had fifteen good strong colonies when swarming time was over. They did very badly as to honey-gathering. It rained all the spring. They could gather only enough honey to raise brood. Out of the 14 colonies, I have not taken 10 lbs. of honey About three weeks since, my bees began to die. I could find a few dead bees around the entrance for several days, then they began to die by the thousands. In the morning I could scrape up a pint on the alighting-boards. I had only two colonies affected badly. I sulphured them, and the rest have nearly or quite quit dying. When they were at their worst they would come out of the hive pellmell, sputter around on the ground, and "pass in their checks." Well, I will tell you I was in trouble. I read my A B C, got an armful of GLEANINGS, and read nearly all night, trying to make it out foul brood, but gave up in despair and did not make it out at all. Can it be something that they get that poisons them, or is it some disease? It is not foul brood, as it is the old bees that die, and not the brood, as the combs are clean and nice; but the quantity of dead bees created such a horrid stench I was sure it was foul brood for a while. Well, it is not on account of queens, as some die at all the hives, and I have several queens I bought this year, some from Louisiana and North Carolina, and one from Thomas Horn; and a few die at all of these, but not many. You can put me in Blasted Hopes if you please, but I am sure it is all for the best, though I can't see where it comes in. I am discouraged, but will keep on trying another year, if the Lord wills it.

Loudon, Tenn., Sept. 22, 1886. W. K. JAMES.

To be sure, it is not foul brood, friend J., and I am inclined to think that, from your description, it is no disease at all, but that they have found something that poisons them. I judge so, from the sudden way in which they began to die in such numbers, and from the fact that it is mostly confined to 2 colonies. Hasn't some one near you left Paris green about where it might get mixed with something sweet? Or, has not some poison, with an admixture of sweet, been left around where the bees can get at it? We have had a few such reports before, but I believe we never found out just how it came about. I would by no means sulphur the bees under such circumstances, for this can accomplish no more than killing the queen. If I had such a case I would confine the bees to their hive, and feed them on sugar syrup. If that stopped it, I should be sure that it was caused by something they gathered. Under some circumstances it might be well to take all other combs and give them new combs, and feed as above. I think this would surely stop it, and you would save your bees.

THE FIRM OF JANE MEEK & BROTHER.

A Serial Story in Ten Chapters.

BY REV. W. D. RALSTON.

CHAPTER X.

EXCELSIOR.

IN recording the events of the summer it was said that one swarm had gone to the woods. It was not one of the first swarms, still it was a fine large swarm. It came off, was hived as the others had been, and all appeared to be going nicely; but the next morning the children were surprised to see the swarm come out. They called their father from his study, but he reached the yard merely in time to say good-by to the departing swarm as it started for the woods. Tommy ran beneath it for half a mile or so; but when it got fairly under way it left him. Mr. Meek stood at the front gate and watched Tommy as he ran. He thus formed a pretty correct idea of the direction the bees had taken. Almost one and a half miles distant, in that direction, a neighbor was building a new barn. The men were now at work upon its roof. Mr. Meek saw that, if the bees continued on in the course they had taken, they would pass directly over that barn. He and Tommy drove over to the barn and inquired of the workmen, who told them it did pass directly over the barn.

They then concluded to examine a piece of woods that lay in its course only a little further on. They were going through the woods in the line the bees were on, examining every tree, when they found them in the hollow of an old snag of a tree, not very far from the ground. They spoke to the owner of the woods, who said they were welcome to cut it. They returned home, and, after dinner, took the ax and a new hive, and proceeded to the woods. The farmer who owned the timber came to their help, ax in hand. Soon the tree was cut, and the bees successfully hived again. They expected to let them remain until dark, when all that were out would have returned and found the hive, when they intended to return and move them to their apiary. The owner of the farm offered Tommy four dollars for it if it remained in the hive; but if it should go away, he would give up the hive and pay nothing. Tommy accepted his offer, and Mr. Meek directed the farmer how to remove the hive to his house, which was not far distant. He also gave him advice in regard to caring for them.

As the honey season was now ended, the firm looked around for a market in which to sell their crop. Mr. Shaw, the grocer who purchased last year's crop, was ready to take all the comb honey at the price paid last year, fifteen cents a pound. Extracted honey was something new to him, and he did not know what success he would have selling it. He gave the children two dozen glass jars, holding three pounds each, telling them to fill these and he would try what success he could have selling them. He paid them ten cents a pound for what he received.

One day Jane and Tommy took a quantity of extracted honey in their father's buggy, and drove around among their friends and neighbors, offering it for sale. They succeeded so well that they went out for several days. As they were introducing a new article they offered it cheap, asking only ten cents a pound for it. In a little time they had sold all their extracted, except fifty pounds, reserved for home use. They also reserved forty pounds of comb honey. The rest was sold to Mr. Shaw. Their books were then posted, and showed as follows:

Bought for the apiary:

10 hives in the flat, 85 cents each	$8.50
1000 sections	5.50
14 lbs. of foundation	6 00
Paint, oil, and nails	2 00
Freight	1.25
Honey-extractor and knife	3.00
	$26.25
Cash on hand from the sales of last year	29.40

Taking from this the expenses noted above, there was left $3.15 in the hands of the firm. Their cash account for this year shows as follows:

One colony sold	$ 4.00
450 lbs. of extracted sold	45.00
510 lbs. of comb honey sold	76.50
Beeswax sold	1.50
	$127.00

Add to this the $3.15 in the hands of the firm, we see that, at the close of the year, the firm had $130.15, and 13 colonies of bees.

On looking over the supplies on hand it was felt that $30 15 would provide all needed supplies for the coming year, and that the firm might withdraw the $100 and apply it to something else. The great question now with the firm was, What shall we do with this money? Sometimes it was proposed to loan it, or to place it in the bank; other times they were thinking of investing it in a pony; at other times they thought they would buy an organ with it; but at length, by the counsel of their father and mother, they made a very good and sure investment of it.

The congregation Mr. Meek served esteemed him very highly, and contributed liberally toward his support; but they were few in numbers and limited in means, and therefore the salary paid him was no more than sufficient for his support. As his children grew up he felt that soon they must go from home to school, or else be satisfied with the education obtained in the common-school. Having received a thorough education himself, he was anxious that they should enjoy as good opportunities as he had. But he failed to see from whence the money would come to pay board and tuition when they should leave home.

After they engaged in keeping bees, and their efforts seemed likely to prove successful, both he and his wife had hopes that the money soon to be needed might come from this source: so when the firm had $100 to spend, the parents proposed that it be spent in sending Jane to the school in the neighboring town. Tommy readily agreed to this; and as the school had opened, no time was to be lost. That very afternoon the whole family drove to town and came back without Jane, who immediately entered upon her duties as a pupil in the school. She had diligently improved her advantages in the public school, and at home; and after being examined by the teachers in town she was placed in a class which would finish the course of study prescribed in that school in two years. A boarding-place was found for her in the family of a friend; and as she remained only from Monday morning until Friday night, said friend charged but $1.50 a week. The bill for tuition was $6.00 a term, so it seemed probable that the money earned by the busy bees would pay all her school-bills for a year, and there would still be some of it left.

Tommy entered the public school at home, and pursued his studies diligently. Still he was lonely without his sister, and it was always with a glad heart that he left school at recess on Friday evenings, and hastened home to bring his sister from town. Those drives home were very pleasant, and each longed for Friday to come. Tommy told Jane the news of his school; she listened with pleasure to him as he related all the little school incidents which had occurred among the boys and girls she knew so well; and in return she gave Tommy the news about the town school, which interested him, especially in view of the fact that he intended to go there himself, if spared.

Monday morning Mr. Meek usually took Jane back to town, while Tommy went to his own school; or, if he could not, this work also devolved upon Tommy. It would be difficult to find two happier children than they during that winter; and one source of their happiness was the thought, "Jane is being educated at our expense."

Their attention to business had made them thoughtful beyond their years. Of Tommy, people often said, "What a manly little fellow he is! and what an idea of doing business he has for one so young!" Jane was often called a thoughtful child, and was commended for her quiet, ladylike ways. It is not known how much their doing business for themselves contributed to make them the children they were. It is very probable that, without their father's aid and counsel, their bee-keeping would have proved a failure. But still that aid and counsel was given in such a way that Jane and Tommy felt they, and not their father, were the real owners of the apiary.

Recently the firm had subscribed for a periodical devoted exclusively to bee keeping. They felt sorry they had not done so sooner, as in it they found so much instruction in the art. Through it they learned of books which they felt certain would well repay them if they should study them, and they determined to purchase them as soon as they were likely to have the time to read them. Jane's school would be in session eight months, and then there would be a long vacation;, and, fortunately, that would come in the season of hurry in the apiary. After she had spent two years in that school the children would change places —Tommy would go to school, and Jane would tend to the apiary. After both had finished the prescribed course in the town school, if more instructions were desired they must attend a college. For years their parents had been hoarding a little sum of money, and adding to it from time to time in hopes that they might give their children the advantages of a collegiate education; but until this business of keeping bees seemed to prosper, they could see no prospects of their hopes ever being realized. Hope had now sprung up in their breasts, that one day their children might be enrolled among the graduates of some good college. If their bees should increase steadily for the four years the children would be in the town school, they would have quite an apiary; and could not the children then attend college, while a man hired for that purpose would care for the apiary under the direction of Mr. Meek, and the honey-crop be sufficient to pay the expenses of the apiary, and also do something toward paying the college expenses of the owners? It seemed probable to Mr. Meek that such a result might be attained, especially as the long college vacation would come at a time when the children's help would be very useful in the apiary.

Will the hopes of these parents ever be realized? We can not tell. Will their children ever receive the expected and desired education? We see no reason why they should not. So far their apiary has made a steady growth, and has been remunerative. This may continue, or a disastrous winter may leave them only empty hives. When we look at what has come out of that old nail-keg, it is difficult to tell what might still come from the same source. Here, then, we will take our leave of the firm of Jane Meek & Brother.

We feel almost sad to think of for ever bidding adieu to Jane and Tommy; yet with the correct principles they have so far received in life, we feel sure they will not only succeed in bee culture, but that they will succeed in being ornaments to their home, to their neighborhood, and to their country. Some may object to this little story, because it gives too bright a view of bee culture as a business; that is, the progress seems to be more steady and sure than we find it in real life. To which I would answer, that the writer has taken a couple of *good* children to start with; and a couple of good children, carefully instructed and directed by Christian parents, do almost invariably succeed in whatever they undertake. Note, also, that the end and object of their prosperity was not fine clothes; it was not a pony and carriage—not even an organ; but the funds were to be used to complete an education so well begun. Could it well be otherwise than that God should smile on such an undertaking, and bless those young lives? In fact, is it any thing more than working out the promise given in the first Psalm? May God grant that many homes in our land may have just such young people as Jane and Tommy! And may such men and women as they make when grown up be found ready, when the times demand them for the safety of our nation.

THE GREAT MORAL PROBLEM.

MRS. CHADDOCK TELLS US OF SOME OF HER LONGINGS AND ASPIRATIONS.

I WANT a boy; I want two boys; I want three boys; I want four boys; I want five boys; I want six boys: I want a dozen boys. I want to take them when they are six years old, and keep them till they are fourteen or fifteen. I want to take a new one every year, so that, when they begin to graduate—*i. e*, leave me and go out into the world, they won't all go at once. I want these boys to work for me, and for their work I want to give them their board and clothes. I know that there are thousands of boys who do not have good clothes—not regular food nor decent clothes—and they would be much better off out here on the farm than they are in the large cities.

"But, why don't you get them then?" you ask. Because I have a conscience a mile long, and it won't stretch nor bend for any thing. Now, if I take these boys to raise, my conscience will force me to send them to school every day as long as school lasts, and I can't afford to board and clothe and educate other people's children, in return for what work they can do for me "between whiles." I can hardly afford to send my own children to school all the time. But if I have one hobby that I think more of than any other, it is that all children should be educated. When mothers talk to me with tears in their eyes, and say they can't send their girls to school, I tell them they can if they really want to. I tell them they can do without tea and coffee, lace and ribbons, and quit trying to put on style till after the children get their education. I want people to work and earn money, but I hate to see people looking through colored glasses all their lives; and uneducated people wear colored glasses as long as they live. And with this conscience of mine, and these educational views, you will see why it is that I can not have my twelve boys, but must go on taking all my own steps till I almost drop with weariness, while in all great cities are those very boys going to waste for want of the food and clothes and right principles that I could give them just as easily as not. **MAHALA B. CHADDOCK.**

Vermont, Ill.

Why, my good friend Mrs. C., it surprises me somewhat to hear that you have been studying on this same problem that has lain so near to my heart all the years of my life; and of late, boys have been coming to me, begging for something to do; yes, and guardians have been bringing them to me, and beseeching me to take them under my care and tutelage. I, too, like yourself, love to make every thing pay; but we might as well give up at the outset in thinking of making a boy pay his way when six years old, and go to school. He might pay his way at home with his father and mother, but he can not with anybody else; or even if he could, who would want a boy six years old to pay his way? May God help us when we get tempted to bend every thing to money-making to such an extent as this. It is true, however, that a boy might earn enough from 15 to 18 years of age to make up for what he did not earn when from 6 to 10 years of age; and this is often done by adopting boys. But there seems to be a good deal of unpleasantness on both sides, so I don't see how it can be done on a large scale. There is no good substitute for flesh-and-blood fathers and mothers. Boys of 12 to 15 may be found who can earn enough nights and mornings, by saving steps and otherwise, to pay for their board. I say they *can* earn enough nights and mornings to pay for their board; but the sad part of it is, that a good many of them *won't*. Others will for a time, but after a while they get tired of it. We pay such boys from 6 to 7½ cts. per hour, according to their value; and by getting up early they can work three hours in the morning, and perhaps two at night. This would give them from 30 to 37½ cents per day, and such boys can generally find board and lodging for this sum. During a vacation, however, by putting in ten or twelve hours a day, instead of five, our young friend may be able to earn enough, after paying for his board and lodging, to clothe himself decently for the year. But this gives the boy no time for play or amusements, and little or none for reading, aside from what he gets in school; and with some boys this seems pretty hard. Others, however, who regard their choring and other kinds of work during the five hours as recreation and amusement, will get along very well, and this latter class as a rule are the boys who make our great men. Almost every boy we get, sooner or later wearies of being messenger-boy for the establishment. I did find one boy, however, who said he enjoyed the position, because it gave him exercise, both of body and mind; of body, by seeing how quickly he could execute commissions off a mile away or such a matter; of mind, by cultivating his memory by making it a study to remember every word that was told him, and to discharge every commission faithfully. That boy is climbing the ladder, and I expect to see the day when he is *away up*. I hardly need tell you that he is a faithful, earnest Christian, and when he works to please others he works with the thought in his heart that it is all for the Master's sake.

REMEDIES FOR BEE-STINGS, ETC.

ALSO SOMETHING IN REGARD TO DOSING WITH PLANTS AND HERBS IN GENERAL.

ON page 667 and 668, GLEANINGS for Aug. 15, the request is made for a temperance remedy to remove the serious effects of bee-stings. I have heard the common plantain-leaf highly recommended. The juice, or warm tea, is to be taken internally, and the affected part may be bathed with it, or bruised leaves applied. A temperance friend told us of a lady whom he found in bed, very sick from the effects of a sting (I think it was a bumble-bee sting). He gave her a tablespoonful of the juice, obtained by pressing the bruised leaves, and in a short time she was better, and able to get up and get dinner. I do not think any bad effects could come from its use, as it is common to cook it for greens.

We have three stands of bees—two black and one Italian. We got the queen from you in June, 1885. Our main honey-crop generally comes from white clover; and as it was mostly over they did not gather enough for winter, and we had to feed them. We did not get much surplus honey this season, and no swarms till Aug. 26, and then the Italians cast a swarm when we thought it was entirely too late in the season for bees to swarm. My husband gave them brood frames with fdn. starters, as he did not have any frame of brood handy to get. The next morning they came out and went to the woods in a hurry. They did not build a bit of comb. The old stand is in a chaff hive. The bees are gathering some pollen, but that seems to be all they can get now. **M. E.**

Boonville, Ind., Sept. 11, 1886.

I have given the above to illustrate what seems to me to be a very common fallacy, not only in regard to bee-stings, but for diseases in general. The afflicted person in this case took a table-spoonful of the juice of plantain-leaves, and soon got up and went to her work. Now, I am well satisfied that she would (or, at least, *could*) have arisen and got dinner, without any juice from the plantain-leaves at all. A table-spoonful of the juice would not affect a well person one way or the other. The proof is already given in the fact mentioned, that plantain-leaves are often used for greens. The greater part of all these plants and herbs are harmless. A person might drink the juice or eat the leaves in almost any quantity, without perceiving any effect whatever; and I am inclined to think the different kinds of herbs used in medicine—at least the greater part of them—produce absolutely no effect whatever. It is true, we have some plants that are poisonous. In that case a small dose produces some effect on the system; but how often does it happen that the effect produced has any thing to do in making the disease better or worse? A dose of lobelia tea given to a person with a bad cough may produce a sickness at the stomach, enough to stop the cough. There is sense and reason in this; that is, the cough is diverted, or stopped for the time being. I do not think the poisonous plant accomplishes any thing further than this. You may say the cough does not commence again after the influence has passed off. To which I reply, that if you by a powerful mental effort keep back the cough—that is, do not yield to the inclination to cough, the inclination will, after say fifteen or twenty minutes, cease of itself. The result accomplished is, as I understand it, the same in both cases. May be I am wrong in doubting whether catnip tea has any influence whatever in easing the pains of the little one; but I should like to see the matter thoroughly investigated by competent medical authority. Very likely the dose gave relief; but may it not be that it was the sugar and milk and water, instead of the catnip? I should like to see the whole matter of doctoring with herbs and plants sifted to the bottom. No doubt they are harmless; but is there any virtue in them at all? We tender you our thanks all the same, good friend E., for suggesting a temperance remedy for bee-stings; and while I am about it, permit me to seriously doubt that even the whisky had much if any thing to do with the recovery. People have serious times with bee-stings every little while; but they almost invariably recover after a little, and the recovery is, as a matter of course, almost as sudden as the approach of the disagreeable symptoms.

SUNSHINE IN OUR HOMES.

ALSO SOME SUGGESTIONS FROM FRIEND TERRY IN REGARD TO GASOLINE-STOVES.

FRIEND ROOT:—In my last letter I spoke of pure air in the working part of the house, where our wives and daughters spend much of their time. Of course, it is needed in the rest of the house also, particularly in the sleeping-rooms. We should take pains to have every part of the house well ventilated at all times. Like you, I *will* have fresh air. It is too blessed a gift to be despised because it costs so little. Many a time have I come in from active work outdoors, in the winter, feeling vigorous and clear-headed. Very soon I would feel right the reverse. Then open go all the doors and windows, so the wind can sweep through for a few minutes, changing the air almost entirely. My wife and daughters being in the house all the time hardly notice that the air is becoming impure, it comes on so gradually.

But there is one point I wish to bring out at this time which is fully as important as good ventilation; and that is, plenty of sunlight in our homes. It is time more were written on this subject, as it is getting to be so fashionable to shut out every ray of sunshine from our dwellings, with blinds and thick curtains and shades. Blinds are nice, and so are shades, if rightly used, which would be to shut out the sunshine during the middle of the day, or when the direct rays shining on us would be unpleasant. When they are used to keep rooms almost as dark as night, for fear of fading the carpets or furniture, or for fear the young ladies may get a little color on their hands and faces, then their use becomes an abuse. Is a little color in the carpet of more account than rosy good health? The exact reason for it, and the exact way in which sunlight has a sanitary influence, is not known yet; but the fact is acknowledged. Dio Lewis once wrote, that at the rear end of his parlor it was not so dark but that one could easily see to read fine print. At that point he put a bracket on the wall and transferred to it a plant from the window. In four days it looked sickly; in two weeks it was yellow; in five weeks it was apparently dead. Another plant was placed on the center-table, about in the middle of the room, and at the end of five weeks that had lost its healthy color, and was evidently failing. "The girls in our parlors," he says, "who were not out more than an hour or two a day, on the average, when the sun shone, were as pale, yellow, and sickly as the plants, and we think for the same reason—a lack of full strong light." The same writer also says that he has cured many cases of rheumatism by advising patients to leave bed-rooms shaded by trees or piazzas, and sleep in rooms constantly dried and purified by the direct rays of the sun. Doubtless shaded houses are responsible for much of the pale, feeble, nervous, and neuralgic condition of wives and daughters. I once heard a celebrated lecturer on home surroundings say in substance that our homes should be hid among trees, so as to be scarcely discernible to the passer-by; that the home should be a nest, so to speak, and hid away as the bird hides hers; that nothing is more unhomelike than a fine building standing out in full view of every one. This is all very nice; but the bird stays hid away in her nest for only a short time. The most of her life is spent in the broad sunlight. Our homes where we spend so much time can not be perfectly healthy, and be hidden away from the great source of all life and heat. Trees should never stand so near our dwellings that the sun can not shine for a part of the day into every window that it can reach. If we allow them to we must not be surprised if we are troubled with inflammatory and nervous diseases. And it will be the same, of course, if the sun is kept out with blinds and shades at all times. Such is the great law of health; and if we violate it, sooner or later the penalty will have to be paid.

Your home, like mine, friend Root, stands out where the health-giving sun can shine in at every window, and I have no doubt your wife lets it in, in liberal doses, just as mine does. As for the carpets, I tell her to let them fade; that it is better than faded children. In the morning my wife throws open the bed in our room, and the blinds and curtains on each of the four large windows, and lets the sunlight stream in. I can hardly get her to open up the parlor as much, in the summer time; but then we do not sit in there a great deal. If I remember rightly, your house is built on something the plan of mine, so as to give as great a chance as possible for light in each room. If I count correctly, the carpenter had 18 corners to turn in boarding around the outside of the lower story of our house. This costs more than a more square style; but it can be made more healthy and pleasant. We like shrubs and flowers in abundance, but will have no trees where they will keep the sun from any window. We have blinds on them all, but we try not to make a bad use of them. One need not live directly in the rays of the sun. It is enough if the sunlight comes into the room freely during at least a part of every pleasant day.

Seeing you press me, friend Root, for my opinion about gasoline-stoves for kitchen use, I must say that I think there is some risk in their use; very little, perhaps, if they are always properly used; but there is the rub. "To err is human." A good lady living in my town wrote to her insurance company once for permission to use gasoline in her house. The reply was, "If you wish to take the chances of becoming an angel suddenly, we do not object." One thing is certain: There are accidents from their use almost daily, while such an oil-stove as the Monitor I believe to be perfectly safe in any hands, if a high grade of oil is used. The manufacturers assured me they had never known of a single explosion, although they have sold hundreds of thousands during the last 12 years. From the make-up of the stove one can readily believe this. Therefore I bought a Monitor oil-stove instead of a gasoline. It is a very little more trouble, as one has wicks to see to; but it does its work well. And then we all want oil in the house any way, to burn in lamps, and it's an unnecessary trouble and expense to have two kinds of burning-fluid. I presume you keep them to sell, friend R., and so would not think of this. With me it would make quite a difference. In all probability you will never have any accident from the use of gasoline; but you *may* have, and I think you are more likely to have than from the use of oil. But perhaps I am over careful.

Hudson, Ohio, Sept., 1886. T. B. TERRY.

Friend T., your suggestions in regard to sunlight bring to mind my recent hobby of greenhouses, cold frames, etc. For several years back, for some reason unknown to myself, I have craved sunshine. When I am reading or writing I am never so happy as when the sun happens to strike on my bald head; and when I felt so strongly drawn toward the subject of greenhouses a year or two ago I could not explain it, only I knew that I felt happy on a winter's day to get right under the full blaze of God's great luminary. Is it not true, that Nature herself often prompts us to these queer likes and dislikes? I want to be in the sunshine with my coat off—yes, hat off too; and if it were not for the appearance I should make in public I do not know but that I would go bareheaded a great part of the time in summer when outdoors.—In regard to the many angles which you speak of in our houses, I used to object to it, often quite vehemently; but since your suggestion, that these angles give us more windows for each room, and windows facing toward the different points of the compass, that we may have more air and more sunlight, I begin to feel quite reconciled to the idea. There are five different openings in our bed-room, for the entrance of fresh air; and air is passing in and out of all these openings the greater part of the year. My wife, like your wife, throws the bed-clothing open to the breeze and sunlight every morning of the year; and the unusually good health enjoyed by the household demonstrates that the practice is certainly not an injurious one.—In regard to coal oil and gasoline, I thank you for having presented the subject to us. With my wife's management I have no fear at all of any explosion; but Huber has ventured to undertake to manipulate our gasoline-stove a good many times. Once he turned the faucet of the large can that holds our supply of gasoline; but it was kept in a small stone room on purpose to avoid accidents, so of course he did not do much harm. He has, however, once or twice turned the gasoline on when the stove was not lighted; and had we not opened the doors and windows of the room where the machine is placed, until the fluid could evaporate and blow out, we might have had a serious explosion. I begin to think, from what you say we had better make a change at once in our household.

MR. THOMAS HORN.

WHAT HE IS DOING, AND A WORD OF ENCOURAGEMENT FOR HIS CREDITORS.

I PRESUME most of the sufferers by the above-named gentleman are aware that he does not answer letters, make any reply, nor do any thing, unless he is absolutely obliged to. Well, the friend who writes below suggests a means of making him (and not only Mr. Horn but every-one else who goes into a like "speculation") attend to business.

Friend Root:—As I wrote you some time since in regard to my transactions with Thomas Horn, I will now finish it after receiving so many promises but no bees. I made a sight draft on Mr. Horn, and inclosed the same with all of his letters to me, and sent them to an attorney in Sherburne. I also wrote Mr. H., that, if he did not pay my draft or send the bees, I would report him to the postoffice authorities. He at once sent 6 frames of empty comb. They may have had some brood in when he started them, but none when I received them. There were about two pounds of live bees when they arrived, and one pound of dead ones. He sent one queen and four queen-cells about ready to hatch. I put them in two hives and gave a frame of brood and honey to each, and have fed ever since. That was August 1st. Now I have two fair swarms that I think I can winter; they are finely marked Italians. If Mr. Horn had sent in May, when he contracted to, I think all would have been satisfactory. M. MCDANIEL.

Ft. Recovery, O., Sept. 21, 1886.

I did know that, under certain circumstances, the U. S. postal authorities would refuse to deliver mail to parties when engaged in swindling operations; but it didn't occur to me until just now that we could oblige such men as Mr. Horn to give some kind of a civil reply to complaints by the above process. Perhaps some of you may think I am hard and severe; but we have waited patiently for Mr. Horn, and have published his promises and kept back complaints by suggesting that he would fix every thing in time, until we have received the censure of many good men. I may add, that Mr. Horn has secured the claim we have on him personally, to be paid some time hence. Now let him make arrangements so as to secure the rest who have sent him money and don't get any reply, or take the risk of having his work during the past season submitted to the postal authorities. I am inclined to think that the amount he is now owing is not very much, and that he could, if he would, fix it all in the way I have suggested. Some of the friends may think, as I have already suggested, that I am getting to be terribly severe; but, my friends, we wish to have every bee-man who reads the journals understand that he had better have a severe attack of the yellow fever or Asiatic cholera than to go deliberately into another Burch or Horn operation and hope to get through it "scot free." "The way of the transgressor is hard," and it is our duty to see that it remains hard—so hard, in fact, that those who are tempted may conclude it will not pay, and give it up, even before they start out.

OUR BEES AND OUR NEIGHBORS.

SOME SUGGESTIONS FROM FRIEND HEDDON IN REGARD TO THE PRINTED LEAFLETS TO BE SENT TO OUR NEIGHBORS WHO ARE NOT BEE-KEEPERS.

READER, please turn to page 619 of this volume, and read in numbered paragraphs friend Cameron's address to his neighbors—an appeal intended to enlighten, and make peace and friends. Also please read friend Root's foot-notes to the paragraphs in question. Now turn to page 695, and read what I have to say near the bottom of left-hand column; also the editor's foot-notes again, and you will then understand the motive which inspires these remarks.

I will now endeavor to pick out and comment upon the sections that I believe will harm any bee-keeper who presents them to his neighbors. If all "neighbors" were like unto the spirit of the originator of the paragraphs in question, the case would be far different; but wise men take the world as it is; and while doing their part to reform the bad, and to bring the morally blind up out of darkness, they yet see the necessity for firmly and rigidly, though kindly, *demanding* all that belongs to them.

THE OVERTURE.

As it is so very rare that bees enter houses and "sting the baby," or any one else, unless pinched, I would have omitted this needless scare.

Section 1 suits me.

Section 2, I would have omitted the last line, as the one preceding it is true, and covers all the ground in this case, and this last line is needlessly prejudicing against the character of our business.

Section 3 is good.

Section 4 might have begun with, "If, by negligence, the bees have once gotten into your kitchen," etc. Let the neighbor understand that the fault is *his*, not *ours*. We can't control the whereabouts of our workers, and yet we consider our business legitimate.

SECTIONS OF DEFENSE.

Section 1, good.

Section 2, tiptop.

Section 3. Never use this section, unless some one in your vicinity has made such a charge. Never put yourself on the defensive until you are attacked. This is a characteristic of the sheep, and is the cause of so many "sheep-dogs."

Section 4. Don't use the word "nuisance;" say, "an annoyance." When an annoyance reaches the "nuisance" point, it becomes removable by law, and I claim that bees never are a nuisance, and never will be, except where they are kept so close to the rightful passageway of others that they use their stings in defense of their homes.

Don't say a word about "poison." This puts the public—the good, the bad, the jealous, the revengeful, and the half insane, all in mind of a secret way to injure, to get up a commotion, and to see what they can do. The neighbor who would lay out poison for bees should be imprisoned; and when you suspect such action, you should spare not money, time, nor energy, to detect and punish the heinous crime; and one of the strong points in detection is not to have your suspicions detected by the villian.

I may be in error; but I firmly believe that circulars printed verbatim from friend Cameron's sections on page 619 will work an injury in any neighborhood where distributed. I further believe, that, with a proper correction, such circulars would do much good in communities where trouble is brewing.

JAMES HEDDON.

Dowagiac, Mich., Sept., 1886.

Friend H., your points are well made; and when we print a new lot of these leaflets we will modify them as you suggest. I think, however, you exaggerate the evil you seek to remedy. Occasionally there are people who will, perhaps, be led to do these very things because our friend has suggested them. It is like the lady who told her children, on going away, not to put *peas in their ears;* and when she got home, every one of the lot had gone and done the very thing she forbade. I do not think, however, there are very many people who would be led to poison bees because they are reminded that such a thing is possible.

HINTS TO A B C SCHOLARS ON WINTERING.

THE IMPORTANCE OF FEEDING, IN ORDER TO GET YOUNG BEES.

IT is probably true, that the wintering problem has been gone over so often that the subject has become stale—at least to the apiarist who always winters successfully; but to a large number of A B C scholars who have not learned how to winter their bees every time, there is one thing they ought to know that has been left untold.

On page 272 of the A B C book, friend Root says, in speaking of the wintering problem: "The main points are, a brood-apartment closely packed with bees, and plenty of good sealed stores. With these two conditions alone, the bees will generally winter all right, even in a hive made of inch boards." Now remember, there is not a word said about the age of these bees. Friend Doolittle says, in his comments on the A B C book, in speaking of the wintering of bees: "Why not feed the whole 20 lbs. in one or two nights, if they have plenty of comb room and plenty of *brood* and *young bees?*" Friend D. hit the nail on the head that time, but he did not hit hard enough. If friend Root had said, "A brood-apartment closely packed with *young* bees, and plenty of good sealed stores," then he would have hit the nail fairly and squarely on the head, but he left out the one essential word.

Now, I do not pretend to understand bee-keeping as well as some bee keepers do, neither do I wish to find fault with my teachers; yet there is one of my teachers called Experience who charged me at least $300 for her trouble; yet I suppose her teaching is the cheapest, after all. What I am trying to get at is this: In many localities, on account of drought or grasshoppers, the bees do not gather any honey after the first of August; consequently the queen soon stops laying, and at the beginning of winter there may be a hive full of bees; but they are old, and their span of life is nearly run. Some of them, probably the larger portion of them, will live through the winter; but, mark my words, they will dwindle to nothing in the spring. In order to show the point clearly, I will give you my experience with six colonies during the past winter. I have chosen this number for the reason that they were apparently good strong colonies on the first of September, each one having a good queen as near like the other as two peas.

For convenience we will number them 1, 2, 3, 4, 5, and 6. About Sept. 1st I began feeding Nos. 1, 2, and 3, about one pint of granulated sugar syrup to each colony every night, and kept it up for about three weeks. After feeding a few days, the queens began laying; the old bees went to work gathering pollen (of which there was an abundance); and when winter came these old bees were mostly worn out and gone; but I had three hives full of *young* and healthy bees that were able to and *did* stand the rigors of winter; and when spring came there was hardly a dead bee in the hives. Of these three colonies, Nos. 1 and 2 were well protected. No. 3 was in a single-walled hive with chaff cushion in the upper story, yet I could see very little difference in the wintering of the three colonies. Nos. 4 and 5 were prepared just like Nos. 1 and 2, with the exception of the feeding; No. 4 was protected, while No. 5 had no protection whatever. These two colonies lived until spring, when they commenced to dwindle—the one that was protected dying first, yet they left in each hive at least 30 lbs. of beautiful thick honey.

No. 6 was in one of A. I. Root's chaff hives; and in four weeks' time, beginning about Sept. 15, they were hauled a distance of 120 miles, attending the fairs; and during 8 days of that time they had all the work they wanted to do; and as they had done nothing for six weeks past, they worked with a will; the queen laid with a will, and they came through the winter with a will to go to work again. This colony was the only one that showed any signs of dysentery, caused, I think, by the honey they gathered at the fairs.

Now, friends, do you see the point that I am trying to show you? With us last season, the grasshoppers were so thick after the middle of July that they nipped every bud and blossom as soon as it appeared, so there was no honey for them to gather at any time in the fall; and, no difference how much honey the bees had on hand, the queens stopped laying soon after the honey stopped coming in.

You see, from what I have said about these six colonies, that protection seemed of little account, and you might think that I do not recommend it. It will certainly pay to protect the bees well, if for no other reason than that the protected ones will not consume as much honey as the ones that are not protected. Sometimes we see that nearly all the colonies in a large apiary will dwindle to nothing in the spring, and yet there will be from one to a dozen that will come through good and strong. What is the cause of it? Here is my reason; and if you have a better one I should like to hear it: There is in every apiary a certain number of colonies that make a business of bringing in a little honey every day, and they get it either by robbing or by some hook or crook; the queen keeps on laying, and they generally winter well too.

The Bend, O., Sept. 1, 1886. **F. W. MOATS.**

I want to thank you, friend M., for your concluding remark; and it is something I have often thought of; namely, that certain colonies in almost every apiary are to be found that always get a little honey, even during the most severe droughts. They are like some business men who manage, by hook or by crook, to take in a little money every day; that is, they will accomplish something each day, when the great multitudes around them seem to settle down to the conclusion that every thing is at a standstill; and I believe as you say, that colonies with extra energy generally winter well. Several years ago there was so much talk of getting the bees to rear brood just before winter set in, so as to have plenty of young bees for wintering, that a good deal of attention was turned toward this one point. Finally, however, several of our veterans gave instances of where bees wintered well when they were queenless during the fall months, and we had one such result. Now, suppose you absolutely prevent all brood-rearing, say after Sept. 1; have a fair quantity of bees, and make all conditions right, are you sure they would not winter as well as those that reared brood during September and October? May be you are right; but we have all of us almost rushed to conclusions when a little more time seemed to show the solution of the great problem was not exactly there after all.

DOOLITTLE'S REPORT.

A GOOD WORD FOR THE MAMMOTH RED CLOVER AS A HONEY-PLANT.

PROBABLY in no year within the last quarter of a century have we had so peculiar a season for honey production in this locality as has been the one just passed. I never have realized so fully as I do now, that successful bee-keeping is wholly dependent upon the weather; for if the weather is unpropitious during a honey-flow, all our efforts in preparing for that flow count for naught. Take it as a whole, we have had cold, cloudy, rainy weather *just* when the bees needed pleasant weather, and pleasant weather when there was little or nothing for the bees to do; so that, had it not been for the seed crop of the Mammoth red clover, I should have had to record a *failure* as to a honey-crop. But, thanks to this source, which came in just in time to save that failure, and enable me to report 33⅔ lbs. of comb honey as an average yield from each colony, spring count.

Spring opened very propitiously, the first 24 days after the bees began to fly being pleasant, beautiful days. This caused the bees to rear brood rapidly, so that most of them were in splendid condition to gather from the fruit-bloom, as their numbers were fully as great as is usually the case at the time white clover opens. But, alas! our hopes were blighted by cool and rainy weather setting in three days before this bloom opened, and continuing till the bloom was past, so that the large force of bees proved only consumers instead of producers, causing me to feed for nearly three weeks to keep them from starving. This unpropitious weather also caused brood-rearing nearly to cease, so that the brood which should have been the best for active work during the basswood bloom was minus; and, feed as much as I would, I could not coax the bees to hatch the eggs the queen laid.

Right here is a mystery to me: How do the bees keep the eggs, laid by the queen, from hatching at one time, and again hatch them so that a hive will be well filled with little larvæ in three day's time? I have noticed this singular fact for years, and have also noticed that feeding bees (at such times as they do not so desire larvæ) to keep up brood-rearing has little if any effect in accomplishing the desired end. Hence I again repeat what I have said elsewhere, that "two or three pleasant days, with plenty of pollen, has more to do with stimulating brood-rearing than weeks of feeding."

Well, when I saw that I could get but little brood in my hives the last half of May, I knew that my crop of basswood honey must be short at best, and especially as we had promise of only about one-sixth the usual bloom; but I was not prepared for such a wholesale loss of bees as I experienced about the 20th of June. Colonies which had started to work nicely in sections during the week of good weather we had the fore part of white-clover bloom were so depopulated that they could scarcely care for their brood; while the ground in and about the apiary was literally covered with dead and dying bees, so that almost every step one must tread on these old worn-out bees, dying of old age. As brood-rearing was now going on rapidly, I expected that again this brood, when hatched into bees, would turn into consumers, as had the brood in the early part of the season; but, as was said before, red clover came to our rescue, which, together with the little gathered from white clover, basswood, and teasel, gave me 2022 lbs. of comb honey from the 60 colonies I had left after my sales during the spring. Out of my 95 last fall I lost 3 during the winter and spring, and two were queenless, which were united with others. From the 60, only 40 swarms issued, so that my numbers to go into winter with will not be greater than a year ago, for I shall unite them down till all have sufficient natural stores for winter. My past experience proves natural stores to be the best for bees to winter upon in this locality, therefore I prefer to use them instead of going through the (to me) tedious operation of making and feeding a large amount of sugar syrup.

Borodino, N. Y., Sept., 1886. G. M. DOOLITTLE.

Friend D., in regard to this matter of getting brood and not getting brood when the brood-nest is well supplied with eggs, I should say the trouble is a lack of pollen. I have succeeded in getting great quantities of brood by feeding flour candy; that is, candy made with a proper admixture of wheat or rye flour. It is astonishing to see the amount of brood that even a moderate-sized colony may produce, when all the conditions are favorable; and it is sometimes perplexing as well as astonishing to see how the bees absolutely refuse to raise brood at times, even though it seems as if we had given them every thing needful.

THE "ZEEP, ZEEP," OF QUEENS.

AND CAN SHE PRODUCE IT WHILE IN THE CELL?

I SEE on page 695, GLEANINGS for Sept. 1, an article from J. C. Gilliland, in which he says: "I have found no queens hatched, even when the queens had been calling one or two days, but with the cap of the cell cut nearly off; and as soon as they were taken out of the hive the young queens would come out." Now, what I wish to say is this: I do not believe a queen in cell ever made a particle of noise; and all talk of the bees keeping the queen in until she squeals is utter nonsense. Now for my reasons:

I have kept bees for 30 years for — well, we will say fun, certainly not profit. I have seen a queen pipe with only a clear glass between us and my face, not more than 6 inches from her, in good light, and she on a clear (almost white) comb. She just stopped, humped herself, and acted mad; vibrated her wings until you could scarcely see them, and "peep, peep," from 3 to 5 times, sounded out loudly. This I saw several times, and at the same time heard others doing the same. The noise is made with the wings; for as the wings ceased to vibrate, the noise stopped; and as the vibrations grew less frequent, the sound was less sharp. Now for another reason: A friend wanted a queen. I went to a Holy-Land swarm where queens were calling. On raising 3 combs I caught and caged 3 queens; and on closing the hive I heard queens still calling. The next day I took out 2 queens, and still heard them calling. Next day they swarmed, and the next morning I found several dead queens in front of the hive. Some seemed to be two or three days old; one, at least, immature, and was undoubtedly taken from the cell. My experience with Holy-Land bees, *got of you*, is that they are remarkably prolific in queens, say from 20 to 30 in a hive. I forgot to say, that, when I saw these queens piping, the bees about them paid not the slightest attention, but just kept at their work as though they did not hear it. Will you, friend Root, or some other person, tell us how the queen makes the noise called "piping"? If, as I believe, with the wings, like the katydid and other insects, then certainly it can not be done in the cell. E. S. MINER.

Necedah, Wis., Sept. 8, 1886.

Friend M., we are glad to receive the facts you furnish; but we want to chide you a little for being uncharitable. I suppose you mean that you will not believe a queen ever made a noise while in the cell until it is clearly proven to be a fact. I do not know that I am just now prepared to give positive proof; but am abundantly satisfied that queens do produce the "zeep, zeep," while in the cell. The squealing may be another matter. I have never watched closely enough to decide on that point. I think I have heard them utter their peculiar note when the capping is loose, so they can push their heads out and draw them back again; and if so, I do not see why they may not do it before the cell is opened at all. I believe most cells would afford the queen room enough to move her wings in the way you mention, and I have supposed this was the way they did it. In fact, I do not know that bees have any other method of uttering their different calls. Worker-bees, you know, express their feelings by the hum of their wings and while on the wing.

* * *

THE POSSIBILITIES OF FRAMES.

THE IMPORTANCE OF SPACING THEM JUST THE RIGHT DISTANCE APART.

"THE invention and introduction of frames formed an era in bee-keeping." Many times has this sentence been written and read; but how many of its writers and readers fully comprehend all it implies? If the bees themselves, and their convenience alone, were considered, it would be found that frames are a disadvantage rather than an advantage. It is to the progressive bee-keeper alone that they are of any value; and to him, that value is incomparable. Frames were originated for the purpose of giving greater control of the bees, and of allowing greater freedom in manipulating for examination and observation. If their value ended with this, I question whether the gain would pay for the actual loss to the producer of honey, occasioned by their use; or whether the discoveries made through their aid would overbalance the actual destruction brought about in the hands of the inexperienced by too frequent examination, and the passion aroused to increase by division till such division ruins their apiaries. But, thanks to the Rev. L. L. Langstroth, his invention of hanging movable frames has been the means in the past of doing more than any other thing to put the occupation of apiculture on a sound and solid basis, and will in the future be the means of giving us full, thorough, and complete control, not only of the bees and hive as a colony, but of causing or preventing increase by allowing or preventing swarming; and also, by the aid of sections and the extractor, of guiding the production of honey in such form and shape as may be most desirable or advisable.

It is a well-understood matter, that the frame hive is a compromise between the natural habits of the bee and the desire of man to control its operations to his best advantage; and for the furthering of this compromise, the only thought *has* been to produce a frame of such form and size as would produce the best yield of honey, and at the same time prove the safest as a winter habitation. To this end discussions have been frequent—as to the relative value of deep and shallow frames. These discussions have at times been warm, and, perhaps as much as any other, have aroused the ire of the various disputants. All of these disputants have, in their desire to prove their particular points, seemed to lose sight of the most important feature of the case, and have been satisfied in fighting over a shadow; namely, an extra inch, more or less, in length or depth. The point they have lost sight of is the space to be allowed between the frames; a mutual agreement seeming to have been arrived at, that *about* 1½ inches, or from 1⅜ to 1⅝, is *about* right.

In this discussion another element has at times been a source of contention; namely, as to whether frames should be fixed or not; and closed-end frames have been used and advised, among which are the Quinby and the Hoffman. One of the chief opponents of closed-end frames, or, in fact, of any frame that is not absolutely movable laterally as well as otherwise, is the editor of GLEANINGS. The position he has taken in this matter is, to my mind, correct, but he has not gone quite far enough. To judge of the future possibilities of frames, we must take into consideration the use that is to be made of them, and work them in accordance with such use. Probably the best results will be attained by using the brood-chamber for brood alone, or at least by doing as the bees do—devoting the center of the brood-chamber to brood, if we use a hive-body large enough for both brood and stores. It matters little what size or form of frame is used, so far as the brood-chamber itself is concerned. It is only when we desire to have our surplus deposited in sections that any question arises; and each one will adopt such size and form of frame as suits himself. The real question is, How can we get the greatest yield of honey in the most desirable form, in the most economical manner, and at the same time bring about the greatest possible increase the most desirably? My answer is, By using care and judgment in spacing our frames. There is no difficulty in getting, by the use of foundation, all combs built true, and, if we space such frames at just the right distance apart, there is no difficulty in having such combs built as flat as a board. Bees will, under no circumstances, seal up brood in cells more than seven-sixteenths of an inch deep. What I mean is, that if deeper cells are given them they will cut them down to that depth before they will seal up brood in them. This being the case, the production of brood is in our own hands; and if we can control the production of brood, swarming is practically within our control. It is not a matter of hives at all. Invention and ingenuity may be taxed to the utmost in producing this, that, or the other style: none of them will be more acceptable to the bees than a hollow log, and none of them will be fully controllable that do not allow of spacing frames as closely together or as far apart as it may be chosen so to do.

To the prejudiced mind, the idea I am endeavoring to inculcate may be deemed "all bosh;" but the thinking mind, who is investigating solely to find the best ways and means, will see that we can accomplish the greatest amount of good only by working in harmony with nature. Many of our humble servants of the lower orders can be trained against their natural instincts, but the honey-bee can not. We can guide or lead it to a certain extent, but we can't drive it an inch. If it has any peculiarities, we can take advantage of them; but we must be sure to do so in the right way. I have already, in a former number, outlined my method of working for honey and increase; and in the above I desire simply to call attention to what I deem a point of importance. J. E. Pond, Jr.

Foxboro, Mass., Sept., 1886.

Thanks, friend P., for the points you make; but I confess I do not see how the production of brood is in our own hands by means of spacing the frames just right. I agree with you, that the thickness of a comb with capped brood in each side is always exact; and it has been suggested that we could make the bees use the combs for brood and nothing else by spacing them just the right distance for the production of brood. Now, while I grant that they are more apt to put brood instead of honey in worker-combs so spaced, it is not by any means certain that they will use these combs for brood only, for I have seen brood-frames completely filled with honey, capped over on both sides, when spaced as you recommend. Very likely, however, they did not have room for their honey in deeper combs at one side or over the brood-nest. If the latter arrangement is to be used in connection with the proper spacing of the brood-combs, may be you are right. I should like to have the matter investigated. We notice that friend Heddon has made the end-pieces of his new hive just $1\frac{3}{8}$ inches. This is done, probably, with the view of accomplishing the object we are discussing.

FROM REPORTS DISCOURAGING TO REPORTS ENCOURAGING.

HOW HE AT LAST SUCCEEDED IN SECURING 500 LBS. OF HONEY PER COLONY, SPRING COUNT.

In giving in my report for the season I might as well commence with the fall of 1884, when I went into winter quarters with 28 strong swarms, 22 arranged along side by side, packed in dry leaves, 6 buried in a clamp. The winter was one of the most severe ever known, and their stores were composed of buckwheat honey and honey-dew. By February, all those packed on their summer stands died of dysentery; the six in the clamp were taken out in April. Four of them were alive, though weak. They commenced rearing brood; but the weather came off cold, and most of their brood was killed, and, of course, the bees were dwindling away until they all lost their queens (I presume they killed them). I united them all, making one weak swarm. I now gave up in disgust, caring little whether they lived or died. I put all the combs away, with the intention of melting them into wax; but the one swarm rallied, raised a queen, and by the commencement of basswood-bloom they were in fair condition.

About this time I bought, for $2.50, a swarm hanging on a tree. They proved to be fine Italians—the kind, you know, that drop several feet away from their hives, and, after getting their wind, go into the hive with that peculiar twist. The queen proved very prolific, and by the commencement of buckwheat-bloom I bought 2 queens and divided my two swarms; and before cold weather they were strong, and had made me 150 lbs. of goldenrod and aster honey, mostly aster, which I think is the finest honey I ever saw. I wintered the four. One was weak, three were strong; they built up very rapidly, and by the 15th of May I commenced to divide, but not to weaken them. By the commencement of clover they were strong enough to work on 20 frames; in about ten days I commenced to extract, and have taken, up to date, 1992 lbs. from four swarms, spring count; and as I have given all the boys and girls all the honey they wanted in extracting days, I call it 2000 lbs., or 500 lbs. per colony. I have increased to 21 strong swarms, and if frost holds off two weeks longer I shall get considerably more yet. M. Vincent.

Milan, Mich., Sept. 13, 1886.

ANOTHER HONEY-PLANT.

ARE THE BEES ATTRACTED BY THE COLOR AND BEAUTY OF PLANTS?

Mr. S. F. NEWMAN, of Norwalk, O., sends me a plant for name which he says is an excellent honey-plant. It proves to be *Polymnia Canadensis*, or leaf-cup. This adds another to the valuable list of the composite honey-plants. It is a near relative of *Coreopsis*, or tick-seed, and of the thoroughworts and goldenrods.

By the way, Mr. Editor, I observe this autumn, that, while our marshes have been resplendent with boneset, tick-seed, goldenrod, asters, etc., the bees have been quite partial to the goldenrods; and if they are governed at all by beauty, why not? I think we have no handsomer flowers in all the floral wealth of nature than these graceful gold-bedecked solidagos. In several walks of late, in a large marsh hard by the college, I have paid special attention to this matter; and while I have seen bees in limited numbers on all the well-known honey-plants, I have seen them *swarming* on the goldenrod. Hence our autumn honey, and we have secured no little of it, is the rich amber color, and most excellent flavor, of the goldenrod honey. Tell *me* such honey is not good for winter stores! I would as soon have it for my own table, or for the bees, as to have the nicest and purest white-clover honey.

I fully believe now that no subject connected with apiculture is so worthy of attention and development as this very one of honey-plants. Next to that I would place the matter of races of bees. I believe careful breeding may give us a much better bee than we now have. A. J. Cook.

Agricultural College, Mich., Sept. 1, 1886.

WHO SHALL KEEP BEES?

AND HOW CAN THE WORLD IN GENERAL BE MOST BENEFITED BY BEE CULTURE?

This subject has been considerably discussed, and I have no intention to take sides for or against invalids and women. The business of raising honey is assuming proportions of considerable magnitude, and it is time to consider it as a matter of public interest, and not merely with reference to the individual bee-keeper. Here is a source of wealth to the nation, not to be despised; a good wholesome food, for home consumption and for export, to be had for the gathering. The public, or, if you please, the state, has a right to consider the best means to secure this commodity in the best shape and at least expense. It is true, that bee-keeping may also be considered as a source of pleasant exercise and relaxation from mental pursuits; but this view is far overshadowed in importance by the other.

As at present conducted, there is a kind of haphazard character about the business of bee keeping. A man keeps a number of bees for a time, and then gives up the business entirely. The same may be said of farming; but in the latter case it is only a change of farmers. In some shape or other the land is all occupied for agricultural purposes.

The public good will be best subserved by having the field regularly occupied; and to this end it seems necessary that the one who engages in the business, be it man, woman, invalid, or servant-girl, shall devote a principal part of, if not his entire time and energies, to bee-keeping as a business. It is a business that requires not only certain natural qualifications, but also thought, study, and experience. One can hardly afford to give these without the expectation of engaging in the business to a sufficient extent to reap a pecuniary reward. Right here I shall be met by some who will say that I must not fail to recognize the right of individuals to engage in bee-keeping, not for the money there is in it, but for pastime and healthful recreation. I do recognize this fully, just as I recognize the right of every merchant, mechanic, or professional man, to have his patch of ground to cultivate potatoes, corn, or strawberries; but the fact remains, that, to make agriculture a source of wealth to the nation, there must be farmers who devote their entire time to the business. Others, again, will think that it is to the interest of certain classes, as publishers and supply-dealers, that bee-keeping should be largely if not entirely in the hands of amateurs. Let us look at this In a given area of, say, 1000 square miles, there might be established profitably perhaps 30 apiaries of 100 colonies each if conducted by 30 specialists. If no specialists were on the ground there might be anywhere from 20 to 200 or more places where from one to a dozen colonies are kept. In the latter case, does any one suppose there would be as many books and periodicals devoted to bee culture taken as among the 30 specialists? And as to supplies, there would be something like a steady trade among the 30 specialists, and among the others the trade would be worth very little. As to the bee-keepers themselves, the sooner the business gets down to an established basis, pursued as a principal if not an entire means of obtaining a livelihood, the better. Those of us who now get our bread and butter by bee-keeping know only too well how the market is annually demoralized by the owner of a few colonies who considers the amount of surplus obtained as so much luck, puts it on the market in any kind of shape, and at any price, doing just so much toward preventing honey from becoming a staple commodity.

I am a little afraid that some of those whose attention I am anxious to secure stopped reading before reaching this point, saying, "I don't see that there is any thing of interest to me in this. What is there practical about it?" It is of practical importance, if my position is correct, to be able to invest time and money in this business, and have some feeling of security that there is some permanence about it; that no mere whim of some envious neighbor may drive me out of the business next year; that, after making investment in buildings and fixtures, and perhaps special pasturage, I may feel secure that no one else may be able, by overstocking, to drive me from the field. In plain words, I take the radical ground that legislation is needed, whereby in some way, under proper limitations and restrictions, by paying for it, I may have the control of a certain number of acres or square miles as a range for my bees. I sincerely believe that something of this kind would best serve the interests of all, and I may have a word to say upon it hereafter. In the meantime I shall be glad if others may consider it of sufficient moment to give their views, even if nothing but objections are given.

Marengo, Ill., Sept., 1886. C. C. MILLER.

Friend M., your ideas are good and sound, but I am afraid it will take a good while to get things into shape as they are in agriculture and some other pursuits. You say, that in farming the ground is all occupied by somebody. It is true, it is occupied after a fashion, but it is not all occupied in the way we market-gardeners sometimes occupy a few acres, *I tell you*. It is a misfortune all around, to have so many who are dabbling at all kinds of industries in this haphazard way—benefiting neither themselves nor the public at large. But so long as this is a free country, it seems hard to prescribe a remedy. By the way, aren't you a little uncharitable toward supply-dealers? I hope that there are few if any supply-dealers (or publishers) who are pleased at the prospect of selling supplies which will probably never permanently benefit the purchaser nor his neighbors. I do not mean to say that we are any more conscientious as a class than other business men; but I do think we are about as good as the average.

REPORT FROM FLORIDA.

FRIEND GRAY TELLS US SOME OF HIS EXPERIENCE WITH PERFORATED HONEY-BOARDS, HIVING BEES ON EMPTY FRAMES, ETC.

EDITOR GLEANINGS:—Although my specialty is queen-rearing, yet a report from ten hives set apart for comb honey may be of interest to some one. This is an "off" year, and, like Mr. Hart on page 645, 1886, I would rather not give figures. Our honey season began with the orange-bloom in March; but this year it seems that the orange trees produced enough blossoms only to make oranges, and no surplus; and there was not more than one-tenth the bloom we generally have. Besides a great deal of unfavorable weather, high winds prevailed; consequently the surplus honey from orange was next to nothing. Saw-palmetto did better, and the ten hives spoken of averaged 20 lbs. and increased to 20. This is all the honey we get till fall.

ORANGE-BLOOM HONEY.

During the orange-bloom, when honey was coming in slowly, my bees got the swarming mania badly, I thought; but the reading of Mrs. Chaddock's, Hutchinson's, and Hart's letters consoled me. I adopted the Hutchinson plan of hiving swarms on five L. frames with starters only; sections with fdn. above, and at side also on a few. I believe four swarms out of ten hived this way swarmed again about one month or less afterward, and I must say the drone-comb built bothered me. I had all the drones reared from choice queens that I wanted;

and I should like to know how much drone-comb in the five-frame brood-chamber it takes to bother friend Hutchinson. I believe he has never been explicit in stating this matter. Some of mine built two frames each, half full of drone-comb; others one frame half full. However, I think the plan a good one; and perhaps another year, if bees do not get the swarming fever, it may work to our satisfaction—anyhow, I shall try it (about 'alf and 'alf).

PERFORATED ZINC, ENGLISH AND AMERICAN MAKE.

I used your zinc honey-boards. Ten of them were American perforated, and ten I cut from a sheet of the English, I suppose, which you sent me. No queens went above either; but I had a queen to pass through the English when I used it as a guard at the entrance. I noticed where I put wide frames with sections and fdn. below, and sections with fdn. above with honey-board between, that they worked best in the wide frames below; but in one instance, where I forgot to put fdn. and sections in the wide frames below, they worked best in sections containing fdn. above the honey-board. Again, one hive was arranged with strips of perforated metal between the brood-chamber and wide frames at the side containing sections with fdn.; also a honey-board separating the brood-chamber from sections above. In this case the bees worked best above. I am well aware, that not much valuable inference can be drawn from experiments with a few hives; but I thought it well to let this be taken for what it is worth.

BROOD-FRAMES 1¼ INCHES APART, FROM CENTER TO CENTER.

I made use of some of the "cream" given us by Mr. Hutchinson from the Detroit Convention last winter by spacing brood-frames only 1¼ inches from center to center. I see Mr. Pond is an extreme advocate of this theory. It worked well with me; it forced the bees out of the brood-chamber; and although honey yielded scantily, I saw no disposition not to work in sections, and I watched closely.

CARE OF COMB HONEY IN FLORIDA.

Nice 1-lb. sections retail at 20 cents. I peddled mine for awhile at 25 cents, but it was slow sale at this price. In this warm climate, in the rainy season the best way I know to keep comb honey is to leave it on the hive above the honey-board, with only five frames below, until you want it. If you take it off and attempt to keep it in a "warm dry room" to keep it from sweating or oozing out, I think you will fail to have a salable article. This is why I have just taken off my last section, although our honey-yield was almost over before it began with a good many. I am now feeding a little to be in good shape for the October and November honey-flow.

Mr. Hart has made a valuable discovery concerning cabbage-palmetto, which he refers to on page 646. Any one thinking of locating an apiary in Florida should consider this piece of news he gives us.

LUTHER W. GRAY.

Orlando, Fla., Sept. 14, 1886.

We are always glad of facts, friend G., even though from the experience of a few hives. If I am correct, your experiments with side and top storing would seem to indicate that the bees prefer to store in sections placed above the brood (but I suppose this, of course, would depend much on the size and shape of the frame). But where perforated zinc is used above, and not at the sides, they prefer side storing. It would follow, then, that, if the queen were kept with perforated zinc from sections at the side and above the brood, the bees would give the preference to that placed above, the same as with no zinc; therefore if our frames are made shallow, we may safely conclude that top storing is sufficient; that is, that very little more honey will be stored by having sections at the side of the brood as well as above it.

ITALIANS VERSUS BLACKS.

SELLING BEES BY THE POUND.

I WANT to say a few words to-day about some of the different kinds of bees—which are the most profitable to keep. My husband has kept black, Italian, and hybrid bees.

The Italians will fly swifter to gather honey than either one of the others; but if there is plenty of honey near by, or so they will not have to go a great distance after it, we think the black bees will gather the most honey.

The hybrids come next. Some years the Italians do the best. Last year we were living in Vermont, and we kept but a few swarms. The Italians seemed to do better there than either of the others —black or hybrid. This summer my husband worked in a large apiary, where there were kept both blacks and Italians. The black bees have gone far ahead of the other bees, and have made much more honey. I think very likely it would depend much on the locality, and what kind of a season it was for bees.

HOW SHALL WE ESTIMATE THE HONEY WHEN SELLING BEES BY THE POUND?

I want to ask a question. Is it right to sell bees by the pound, and sell part honey with them? Suppose Mr. C wants to buy a few pounds of bees. He sends to A or B, who live at quite a distance. Mr. A gets the order, and that day, or perhaps the next, goes to his apiary. Those bees must be got ready to send off; but he doesn't think of that smoker being left behind. No, he does not wish to get stung, if he can avoid it. He gives the bees a good smoking, then waits a minute or so, and nearly if not all of those bees will fill themselves with honey. Mr. A then proceeds to take out the frames, shakes the bees from them into a box; then when they are nicely packed and weighed they are sent off. Mr. C is charged so much for so many pounds of bees, honey and all. What I wish to know is, how many more bees should be put in to make up for the honey? Perhaps this would be called a small thing in the sight of some people in this world, but not in the sight of God, who knows and sees all things. God looks at the little things we do, let them be good or bad, as well as the great.

MRS. JENNIE M. JOHNSON.

Rexford Flats, N. Y., Sept. 20, 1886.

Like a great many other things in bee-keeping, no definite rule can be laid down. Bees will gorge themselves very much in proportion as you smoke them. It is a great mistake—in fact, an act of cruelty—to smoke gentle bees like Italians until they all gorge themselves with honey. In the majority of cases a couple of puffs over the top of the frames will be found amply sufficient. Shake the bees into a pound cage, and then allow about one-fourth to the actual weight of the bees for the honey they may have in their sacks; that is, if your order calls for a pound of bees, make the scales turn to a pound and a quarter. If you propose to cage and ship vicious bees, it may be necessary to smoke them so severely as to cause them to gorge themselves. I would then allow one-half for the honey. Again, in the height of the honey season, smoke or no smoke, gentle bees will be filled with honey. A liberal allowance should then be given as before; at any rate, do not be afraid to give good measure. An interesting point comes in here: We have, in former seasons, bought swarms in the cluster just as the farmers brought them in. We paid so much a pound for the bees, and therefore knew the exact weight of the bees at the time of clustering. On weighing them the next day, to ascertain the amount of honey the bees carried with them, we found that they lost nearly one-half. Of course, the bees had gorged themselves with honey just prior to the exodus of the swarm. The shipper must therefore use judgment.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

BEE-KEEPING IN THE WEST INDIES.

I HAVE just received your A B C book, and "How the Farm Pays." I should like a little advice from you with regard to bee culture. I may say I'm a beginner, and then, again, I'm not. I have 58 colonies of bees in all sorts of boxes, and two hives with bees. The hives were imported from England. With America so near, it is any thing but a paying concern to send to England for bee-appliances.

This is a glorious country for bee culture, there being no winter and only two months in the year when bees have to be fed—August and September. One great drawback is, that the weather is very severe sometimes; consequently the little fellows, not being waterproof, have to stay at home. Among the negroes, bees are kept largely, and they make a good living by it — some of them. One man I must tell you of—a blacksmith—worth 2s. *6d.* per day, refuses to work, because his bees give him such a good income. He has 1000 boxes; and — would you believe it? — sometimes his swarms go away simply because he won't pay 3 pence for a box to put them in. He is "penny wise and pound foolish." I have known his bees to remain three and four days on trees in his yard, and not go away. I have seen the bees working on comb, hanging where they swarmed. To return to myself, I have 60 boxes, and I mean to keep them on an improved scale. In October I expect those 60 to increase to 100. January, when they start fair play, I expect them to be 300 before I take any honey; and by July, the end of the honey and swarming season, if all goes well I expect quite 1000 boxes. I think my best plan would be to start a fresh apiary, letting this one go on the same way. C. E. SCUDAMORE.

Morant Bay, Jamaica, July 28, 1886.

Friend S., we are very glad indeed to hear of so good a report from Jamaica, and I am particularly interested in that colored blacksmith who has 1000 colonies, for I suppose you mean by the term "boxes," hives of bees. If our colored friend has got up to this number of colonies, it seems to me he ought to have intelligence enough to take hold of the A B C book, and I do not know how to give any better advice than for you both to follow its teachings. It is being revised constantly: in fact, we are at work every day in the year, to keep it fully abreast with the times in all late improvements.—If I were you I should not be ambitious to become master of a thousand colonies. Ten colonies, so managed as to give you 1000 lbs. of honey each season, will be better than a large number with little or no honey. Your success depends greatly on your market. What does nice comb honey in one-pound sections sell for in your principal cities?

WHAT TO DO WHEN BEES SWARM IN THE FALL.

Brother Root:—Inclosed find one dollar for GLEANINGS. I really feel ashamed to send so small an amount of cash for so large an amount of instruction. My bees have made but little honey, and have swarmed all the fall. What shall I do with them? I hate to cut out the cells. I had one swarm come out last Saturday, and I let them go off because I did not want them. J. B. PIKE.

Marshfield, Vt., Sept. 5, 1886.

Thanks, friend P., for your kind words. Before we can direct what you should do with swarms that come out in the fall, we should have to know whether you want an increase of stocks or honey. In any case, unless you are already overstocked I think it will pay well to feed them. Late swarms, when properly fed up, winter beautifully, for the queen almost always raises a nice lot of brood before winter sets in.

NOT VERY FLATTERING SUCCESS.

In the fall of 1883 I bought two hives of bees for $10.00. They wintered well on their stands. In the spring of 1884 one of them swarmed once and the other twice, making me in all five good swarms. The same spring I traded a cow, valued at $40.00, on five more young swarms, having then in all ten swarms; but there followed a dry fall, when they did not do very well. In the spring of 1885 six of them were dead, with honey enough in their hives, and the four alive. They dwindled away until they were all gone. That ended my bee-business. In April last I bought a hive again for $6.50, and from that one I now have five good swarms, which have all been doing finely until within about four weeks, when the dry weather came upon us, and which is still reigning, since which time they have gradually been doing less and less, until now they are having actually nothing to do, almost every thing being dried up. Now, what can I do for my bees? Feed them? If so, how?

Elkhart, Ind., Aug. 18, 1886. M. D. WENGER.

I would feed; see Our Own Apiary, last issue.

BLACK BEES WORKING ON RED CLOVER.

I have black bees that work on red clover extensively. One colony has made 70 lbs. of surplus, and swarmed June 28th. One young swarm that I hived June 5th made 50 lbs. by June 27th. This was surplus. Others have done as well. How is that for black bees? I have owned bees 34 years, and since June 12th is my first experience with Italians. In the A B C book I saw your statement that you did not know what propolis wax is gathered from. It is gathered from the quaking aspen, poplar-buds, and balm in-Gilead. Drops of wax can be seen at any season of the year. The bees bite it off with their mandibles, and lay it in the pollen-sack. **James P. Reynolds.**

Hydetown, Pa., July 3, 1886.

WHAT SHALL WE DO IN A CASE OF SEVERE STINGING?

In your issue of Aug. 15th, page 667, you tell of a case of severe bee-stinging, where whisky was given the credit of saving a child's life. I am willing to give "honor to whom honor is due;" but as my youngest child (20 months old) passed through a similar experience one day last week, and recovered without the use of any thing intoxicating, I think it doubtful if it is necessary in such cases. My baby was not unfrequently stung last year, and this without any unusual result; but on the day in question he trod on a rotten apple, and a bee stung him under the foot. In two minutes he was swollen all over his body in an alarming manner. White blotches came out, accompanied by great itching; he had also a difficulty in breathing. We laid him on a lounge in as cool a room as we had, and fanned him, applying hartshorn freely to the foot stung, and in less than an hour the alarming symptoms had subsided, leaving him intensely red all that day. Now, why did it affect him so on that occasion? Was it the extreme heat of the weather, or the condition of the child's blood? or was the bee particularly poisonous? **Samuel R. Neave.**

Hughesville, Md., Aug. 31, 1886.

Very true, friend N.; but when a child or a horse has received 50 or 100 stings on various parts of the body, are you sure your mild treatment would have answered? I am free to confess, that I am very much averse to the use of whisky, or, in fact, drugs in general, in cases of severe stinging; but if whisky *will save* a child's life, then we ought not to hesitate about administering it. I would, however, resort to other means first; and if life still seems to be threatened, I would give the whisky. Perhaps Prof. Cook can advise us.

BEES AND NEIGHBORS, AGAIN.

Barry bee-keepers are in trouble again. They sued my husband in June, about the bees, claiming they are a nuisance; but when they found the bees belonged to me we settled without any suit by agreeing to either move the bees or put up a fence or screen. We put up a screen of muslin and canvas. There is a large cider-house in town where they make a great deal of cider, and also buy apples. They have no screens to the windows, and lately the bees have been pretty thick in the cider-house; as it was extremely dry, there was no honey in the fields. This cider-man and others drew up a petition to have all the bees moved out of town, asking the city council to pass an ordinance to that effect. Now, what had the bee-keepers better do? I understand they have about 200 signers already to the petition. It was circulated lively on Sunday. We have no saloons in town, but this man sells hard cider, and has been tried more than once. There were men in town yesterday who were drunk on his cider. I should like a hundred of your new tracts, but they are not broad enough to cover nearly all the ground in our case.

Barry, Ill. **Mrs. M. A. Shepherd.**

My friend, you are striking on a great problem. How shall we meet these great things? If you should start out with a petition against cider-mills, and in favor of bees, perhaps you could easily get more than 200 signers in a town that has no saloons. In that case, I do not know how the council could pass the ordinance you refer to; but is that the best way to meet such questions? You know the Bible says, "Not by might nor by power, but by my Spirit." Can you not put up screens of cheese-cloth or mosquito-netting around the cider-mill? It seems to me, my good friend, you have nearly the right spirit; and with *God's* help, even one individual is a majority. Is it not so?

THE SUPERIORITY OF ITALIANS AGAIN, OVER BLACK BEES.

The honey crop is almost a failure here. Good colonies of Italians, however, have gathered about 45 lbs. on an average; but black bees have hardly made enough to winter on.

RABBITS FOR KEEPING DOWN THE WEEDS AND GRASS IN THE APIARY.

I have found the rabbits sold by Fradenburg to be a valuable acquisition to the apiary. Last year I kept from 6 to 12 in an apiary of 25 colonies, and they devoured grass and weeds as fast as they appeared. This year I discarded them, and that to my sorrow; for I have been annoyed not a little with a rank growth of vegetation. Methinks I hear you say, "Why did you not hoe up the weeds?" Well, the bees seemed to prefer weeds to slashing around with a hoe. I shall restock my apiary next year with said rabbits. **D. W. Moss.**

San Augustine, Texas, Sept. 4, 1886.

BALLING QUEENS.

I should like if yourself, Ernest, or some of the many writers in Gleanings, would give the cause and remedy of the above trouble. In my ten years' experience with brown bees I never heard of or experienced any thing of the kind; but since I got all Italians, it has got to be almost a common occurrence. I have lost a good many fine queens by balling, and, it may be, through my manipulations —not by introducing queens, understand, but from working with the bees. Give me the cause, and how to prevent it. Are the Italians subject to it? **John H. Mullin.**

Oakland, Col. Co., Texas, Aug. 26, 1886.

Bees ball queens for the simple reason that they do not wish to accept them, and by that means they propose to sting or smother them to death. When a queen is found to be balled, remove the frame to which is attached the ball. With the smoker in one hand send a few puffs upon the ball until you can see the queen. Continue puffing smoke upon the bees so tenaciously clinging to the queen, until you can pick her up by the wings. In doing this, in all probability two or three bees will still adhere to the queen. These you must pick off one by one. In taking a queen out of a ball of bees, a smoker is almost indispensible, though I have done it without one.

DRUMMING BEES.

I am an A B C scholar; and if you will allow me a little space in GLEANINGS I should like to ask you to explain a point in reference to transferring bees from boxes to movable-frame hives, which I, for one, do not understand. On page 269 (A B C book) you say (allow me to quote it word for word, so as to make no mistake):

"A little before swarming time, pry the top from your box hive and set a single-story Simplicity over it, making all the joints bee-tight. Now hang frames filled with fdn. in this new hive, and the bees will soon work up into it. After the queen gets to laying in these combs the bees will soon all move up into it and you can lift it off and transfer, or do what you please with the old hive and combs. When you are hurried, this plan gets your stock gradually into improved hives, without very much trouble, and no mussing with dripping honey."

Mr. Doolittle, in his review of the book, advances just my idea exactly (No. 13). He says:

"Why don't you drum out those bees to start with, and have them out of the way?"

You answer, "Because I like the way I have given, best." Now, Mr. Root, will you kindly give your reason for *not* drumming those bees out at once?

I fear the honey-crop is not coming up to the average, this year, in this locality. I tried sowing buckwheat in front of the hives, but I have never yet seen a bee at work at it, although they go in multitudes to a field of buckwheat from a quarter to half a mile away. W. M. BARNUM.

Angelica, N. Y., Aug. 25, 1886.

Friend B., I would not waste time in drumming bees out, for I can transfer a hive and have it all finished during the time ordinarily occupied by the drumming process. I have thoroughly tried both ways. The passage you quote was only a suggestion to those who prefer to transfer in that manner. Our regular way of transferring is given just before the above, as you may recollect. I should think it probable that, for some reason or other, there was no honey secretion in your own field of buckwheat.

HENDERSON'S SUBSTITUTE FOR GLASS SASHES.

In Feb. No. of GLEANINGS, page 142, you quote from Henderson's price list a substitute for glass sashes for protecting and forwarding plants. Are they safe to use all winter, or only in spring, after glass has been kept over the plants during winter? Did you try stout cotton cloth instead of cheesecloth, as you had intended? If you did, how did it work? J. M. KEHRES.

Dornsife, Pa., Aug. 25, 1886.

Friend K., we did try the substitute for glass a good deal. Stout cotton cloth, well painted with linseed oil, was a good deal more protection than Henderson's thin cloth; but the great trouble with both of them was, that they were blown about by the wind so as to make them practically useless. If they were not blown clear off, the cloth would flop up and down, so as to act like a bellows, expelling the warm air and drawing in the cold air, until the temperature was about the same outside as inside. Stretching it out on a frame, something as we do a sash, would doubtless answer a good deal better; but even then we should have the bellows motion about the same. I have about decided in favor of glass; and early in the fall, or toward spring, as the season grows warmer I would alternate the glass sash with shutters made of light pine. In extremely cold weather these sash will answer to cover the glass for an additional protection, the shutters being used, of course, nights and during cloudy days.

REPORT FROM FLORIDA; O. O. POPPLETON, AND HIS CHANGE OF LOCATION.

Bees are gathering more from the goldenrod this season than I have ever known them to do before. They are also working freely on the cowpea and some small white wild flowers, but are breeding heavily for this time of year, and reducing their store of honey as a rule. The mangrove put on quite a quantity of late bloom, but I do not think the bees got much if any honey from it this year.

Mr. O. O. Poppleton and family have sold out their place in Iowa, and will remove to their property here next month. He intends to bring about 100 colonies of bees with him from the North. He and his wife have spent three winters in this State, and, finding it agrees with their tastes, and promises well for their chosen pursuit, besides greatly improving their health, they now come to remain permanently. W. S. HART.

Hawks Park, Fla., Sept. 13, 1886.

Friend H., our best wishes go with our good friend Poppleton and his family; and we trust he will hold out as faithful and energetic in his work there as he has in the Northern States. We shall perhaps miss him to some extent from our conventions here in the North; but what is our loss, we trust will prove to be your gain.

ANOTHER BEE-KEEPER SUFFERS LOSS FROM FIRE.

This morning, just before daybreak, our little village was aroused by cries of fire; and on looking out we saw the large lumber-mill of C. W. Smith completely involved in flame. Nothing could be done to save the mill—the efforts of the villagers being directed to saving surrounding property. Every thing in the mill was destroyed, including the most of my hive-making machinery, a small quantity of lumber, etc., on which there was no insurance. I shall immediately replace the machinery; and as my storehouse was unharmed, I think I shall be able to fill all orders from that until I get to running again. C. W. COSTELLOW.

Waterboro, York Co., Me., Sept. 9, 1886.

Friend C., I think I shall say again, as I have said before, that, if I could not have my business insured, I would not have the business, unless, indeed, it were a business of such a nature that, while insurance would be exceedingly high, the profits would be very large, and the amount of capital invested comparatively small.

CARNIOLANS NOT STORING MUCH SURPLUS.

My experience with Carniolans is somewhat similar to yours and friend Swinson's. I obtained from Charles D. Duvall two fine queens in June, raised from an imported queen from Frank Benton. One of them proved to be mated with an Italian, and her progeny proved to be very yellow; the other was purely mated, her progeny being a gray in color, somewhat like our old native gray bee, and yet a practiced eye can detect a difference. They both proved exceedingly prolific; bees are good workers, but make very little surplus honey. They seem to consume all extra honey in brood-raising, and for fertile workers they surpass any thing I have ever seen. I have seen as many as one dozen depositing eggs at one time. I, like friend Doolittle, find home-raised Italians the best. T. Graham Ashmead.

Williamson, N. Y.

QUEENS RAISED UNDER THE SWARMING IMPULSE—ARE THEY PREFERABLE?

I have read several times in Gleanings concerning queens raised under the swarming impulse, and those raised in strong nuclei. I have experimented largely on that point, and I *prefer* those *not* raised under the swarming impulse, as they do not swarm so much, which is a benefit to the honey-producer. Now for facts concerning the matter:

In the spring of 1884 I had a very strong colony of Italians, which superseded their queen and swarmed with virgins, three in number. I caged the three virgin queens and returned the swarm. I then turned those three virgin queens in three different colonies, where there was nothing but cells—no queen. They were accepted at once, and the cells torn down; and those colonies, and those where I introduced those queens, swarmed more or less all through the season. In 1885 I tried the same with the same result; also the same result this year, while those raised in strong nuclei swarmed but once, and then came down to solid work. I received more honey from the bees raised from queens reared in strong nuclei or colonies after the swarming season was over than I did from those raised under the swarming impulse.

Josiah Eastburn.

Fallsington, Bucks Co., Pa., Sept. 20, 1886.

MILKWEED HONEY.

I mail you to-day a sample of milkweed honey. My bees have made about a ton of it this year. I do not like its flavor, but think it has a beautiful color. In a larger package it has a very bright golden color. It is, as you see, very thick, but I allowed it to be entirely capped over before extracting. I have never seen mention made of milkweed as a honey-plant, and therefore send you this sample, believing it will be something new to you. Now, don't say I am mistaken, and it is not from milkweed, for I *know* it is. I never knew bees to work faster, or store honey more rapidly, even from basswood. This ton of honey was all gathered in about a week, by sixty colonies. I never noticed this honey until a year ago, when I had a small quantity—two or three hundred pounds—I thought then it was "bug-juice," but know better now. Please pass your judgment on it, and report. I do not think it will be generally liked, for our neighbors nearly all condemn it. Willis Early.

Sherman, Pa., Sept. 22, 1886.

Thanks, friend E. Its color and transparency are beautiful, and *I* think the flavor is beautiful, though many may not agree with me. It seems to me that your neighbors are hard to please, if they dislike honey like the sample sent. I thought at first I had seen samples of honey from the milkweed; but come to think of it, I guess it was fireweed. But how about the little appendages that tangle the bees' feet? In reading your letter, I was surprised that you did not mention them. Didn't your bees get clogged, and fall down to the bottom of the hive, as so many have complained, where milkweed was plentiful? The fact you furnish us is another evidence of what I have often said, that almost every plant that grows is liable to furnish honey whenever we have a year when the conditions happen to be just right for its secretion.

CAN FOUNDATION BE SO MADE THAT THE BEES WILL NOT USE IT FOR BROOD-REARING?

Has the experiment ever been tried, of making foundation of such shape that it will not be used for brood? It seems to me that it can be done. If such could be done, it would be of great practical value. If it has not been tried, it seems to me that, with the means you have, and facilities for experimenting, it would be a profitable field to work in.

Sergeant's Bluff, Iowa. L. M. Brown.

Friend B., if you consult the back pages of Gleanings you will find pages devoted to the discussion of the best size of cell; and for a year or two we even sent out fdn. with the cells made between the size of worker and drone. It answered for comb honey in sections, for the bees rarely if ever tried to put brood in it when used for that purpose; but when used for brood-combs, every little while there would be a cell containing no brood, and on this account the use of it was abandoned.

IMPORTED CARNIOLAN BEES.

I will comply with your request in your foot-notes to J. B. Mason, page 616, 1886, by sending in my report, or experience, of an imported Carniolan queen from last summer, a report of which was given on pages 529 and 596. The queen proved a remarkably good layer, so that, at the time of going into winter quarters, the colony was one of my strongest ones. I fed them about half their winter stores. They were wintered successfully in a Root chaff hive and came out strong. They swarmed June 7th, were hived on empty combs, and soon had eight frames with brood, but almost no honey. They swarmed again July 31st, and were hived this time on frames with foundation. They were examined this morning, Aug. 5, and I found them drawn out about ¼ of an inch, with eggs in two frames, and a little honey in one frame only. Upon examining the hive from which they issued July 31st, I found brood in ten frames, and I don't believe there was a cupful of honey, even if all were extracted. The workers are all of a uniform color, no yellow in the least, and the very gentlest nature. I can open the hive during any part of the day, and remove all frames, without any smoke or veil. They remain quiet, and evenly divided over the combs. The daughters raised from this queen prove equally fertile, and the workers are much better honey-gatherers. I did not get this queen to raise queens for sale, but merely for my own satisfaction.

I think it a very difficult matter to keep this race pure—much more so than the Italian race. I have now in my yard about 15 Carniolan colonies, all raised from this imported queen, and all but a few have yellow bands, and some of these are the prettiest bees I ever saw. Those that have no yellow bands have more the resemblance of our common black bees by lacking the steel-colored appearance, and more or less the bands of down. I have only two strains of bees, Carniolans and Italians. I think they are a hearty and prolific race; and if mixed with Italians they will, perhaps, be an improvement. E. K. BLANK, M. D.

Hatfield, Pa., Aug. 5, 1886.

Thanks for your candid opinion of the Carniolans. Your experience with this new race is about the same as ours. We can not, therefore, think we have been impartial in the statement of their good and bad qualities.

WINTERING BEES IN THE UPPER CHAMBER OF A HOUSE.

I have great faith in your opinion on the general principles of bee-keeping, from the long and extensive practice and experience you have had, and the many methods that have been represented to you of wintering bees. I have had bees more or less for 40 years; but at the time I first kept bees there was no trouble in wintering them. They then took care pretty much of themselves; but for some ten years, or thereabouts, back, I have lost about as many every winter as I gain ahead every summer. I have tried a good many ways that I have heard recommended, and the best luck I have had was something of a chaff or straw protection, or simply a large box put over the hive and stuffed with dry hay between, leaving the entrance open all winter, so that the bees can fly when they wish to. But my success has not been up to the standard I should like. I want to begin in time this season, and try to get what light I can get on the subject. I have been proposing to try the chamber of my dwelling-house. It is the third-story from where we live, a good lath-and-plastered room, some 14 feet square. It can be darkened, and made close. The pipe from two stoves enters the chimney in said room. There is no chance of their being disturbed by jarring or noise. I should like to hear your opinion on wintering in that location. I have also thought of trying some in my hay-barn, packing in hay away up above my horses.

Romance, Wis., Aug. 28, 1886. WILLIAM HALL.

Friend H., putting the bees in an upper room is pretty much discarded. Although they *may be* wintered nicely in a barn, the conditions are so seldom just right for it I would not recommend it. The whole subject is thoroughly gone over in the A B C book; and to put it briefly, unless you put your bees in a perfectly frost-proof repository they had much better be in the open air, where the sun can strike the hives as much as possible. Protection from prevailing winds is also an advantage, and this is best done by buildings and high board fences; but don't cut off the sun unless you can give them something better. I fear the stovepipe would at times make the room too warm, and thus cause trouble.

FOUL BROOD IN A SMALL APIARY, AND A SURE AS WELL AS SENSIBLE CURE.

I notice in GLEANINGS for Aug. 1 that you have foul brood in your apiary, and that you are destroying all combs affected with it, which I think is the shortest and surest cure you can practice. In my experience, one year ago, with the same trouble, I succeeded in curing it with but little time or expense. I will tell the experience I had with it. I will first state, that I was taken sick about the first of February, 1885, and was not able to attend to or look after my 15 colonies of bees till about the middle of June. By this time I had lost 8 of them with foul brood, and the other seven were in a horrible condition when I first looked them over in June, when I was not able to do much work; but by a strong determination I prepared 7 hives with full sheets of fdn., and then I built a small fire by piling old rails and brush together, and then I commenced operations. I went to my first hive and found the queen and caged her; then I removed the old hive from the stand, bottom-board and all, and replaced one of the clean ones, filled with fdn., and laid the caged queen on the top-bars of the frames, and put on my quilt. Then I went to my affected hive and took out a frame and shook off the bees and then pitched it on my fire, and so on until I had the whole 7 treated in the same way, burning up combs and frames, hives, bottom-board, and all. At night I closed in the bees for 48 hours, with a wire screen, and then I let them out and liberated the queens, and that was the last of foul brood I saw among my bees, and I think I am entirely rid of it, as there has none appeared up to date.

Bees are doing fairly in this section. My best colony will make over 100 lbs.; I think they will average 75 lbs. per colony. P. D. MILLER.

Grapeville, Pa., Aug. 7, 1886.

You did exactly right in treating your colonies in the way you did; but with our large number of colonies it would be rather expensive business. We hope to cure it by the treatment we have been giving. Should we fail, however, we may burn every thing except the bees.

NOVA SCOTIA, AND ITS HONEY RESOURCES.

I am a native of the U. S. I came here from Alliance, O., last fall. I have found two kinds of clover which I think bees can work on. The clovers grow very tall—as tall as the large red; the blossom of one is white, the other red. Are these alsike clovers? This is a great country for the honey-bees, but the industry is in its infancy. Wild flowers and white clover are abundant. The main trouble is in wintering bees. I have begun with a new swarm, and the hive—old upright—has in it already at least a bushel of brood and honey.

REV. G. L. RANKIN.

Lunenburg, Nova Scotia, July 12, 1886.

Friend R., we are glad of your report, and trust you may be successful in introducing bee culture into your far-away home. Some years ago we had a correspondent who gave us some very fair reports from Nova Scotia, but we have not heard from him of late.—Alsike clover is much like white clover in appearance, only the leaves and blossoms are larger, and the petals, instead of being white, are tipped with pink. In fact, the appearance indicates just what the plant is—a cross between the white and red clover.

THE VALUE OF A QUEEN NOT DEPENDENT UPON HER SIZE OR LOOKS.

June 11 you mailed me an Italian queen, *untested;* and as you particularly state in your catalogue that you make no choice in sending dollar queens, I mentioned nothing about wanting one of particular beauty, etc. When she arrived, which she did in good time, I must confess I was greatly disappointed, for she could hardly be distinguished from her attendants. Nevertheless I put her with the hive, and the bees having accepted her I watched and waited for developments. She has proved herself a very treasure, having filled every thing with brood, and keeps it up. Now, if she were only a little different from the rest in size, I would not part with her for considerable; but as my frames fit the hives too closely I am almost afraid to open them, fearing that I may kill her majesty while putting the frames back in place. If I could tell her I could guard against any such catastrophe.

A. R. COMSTOCK.

Sayville, Suffolk Co., N. Y., July 19, 1886.

AN A B C SCHOLAR'S EXPERIENCE IN DIVIDING.

I have your A B C book, and have gained a large amount of information from it, but am now in a puzzle.

A few days ago I divided a very strong colony, and made two of it. I put 5 frames in the new hive, about one-half of which was brood, the other half honey. Last night when I opened it to see how they were coming on I was astonished to find the honey *entirely* gone, no sign of any, and a large amount of young bees hatched out, and some dead ones in the bottom of the hive. Now, what became of the honey, and how shall I operate?

Philadelphia, Pa. F. W. TAYLOR.

Your nucleus has been robbed, friend T. When you make an artificial colony, you must be sure that the bees have learned to defend themselves. If you will make the entrance small, the young bees just hatched out will very soon keep out robbers. The best way to feed them to keep them from starving will be by means of a comb of brood, bees, and honey, from the parent hive. Sometimes the bees that are old enough to fly will go back to the parent colony, taking all the honey with them. This may be the case with your bees.

AN UNUSUAL EFFECT OF ATTACHING A DRONE-EXCLUDER TO THE ENTRANCE.

Will you kindly give your opinion on the following case, through GLEANINGS? Last Sunday, Mr. John Oliver, a neighbor of mine, had a swarm come off. He hived them, but they almost immediately left the new hive and returned to their old home. He then put on a drone-excluder in front of the old hive, and went to church, satisfied in his own mind that he had fixed them this time. In the evening, on examining them, he found the combs all down and the bees either dead or dying; but there was quite a lot of bees clustering outside. The hive was under a shade-tree. It had not much honey inside, but combs were well filled with brood. The frames are 12 inches wide by 15 deep, and not wired.

Friend Oliver's theory is, that when, finding the drone-excluder on, they became so exasperated that they ripped every thing to bits, and so brought the misfortune on themselves. My opinion is, that the hive had become overheated, and that the combs, having no wire to support them, had melted down.

We have had a very fine show of white clover this season; but owing to the extreme heat and want of rain it did not last long.

I met with a curiosity a few days ago while driving through the country. I met with a man who has kept bees for over 50 years, and had never seen a queen until I opened one of his hives and pointed her majesty out to him. J. N. KENDALL.

Ilderton, Ont., Can.

Friend K., your drone-excluder is what made the trouble. The colony was probably a very strong one, and the drone-excluder so hindered them from getting out and in that the entrance became blocked, and a stampede ensued, leading the bees to so cover every crevice that afforded air that the inmates of the hive were smothered. In such a case the heat of the hive will run up until the bees, brood, etc., get almost scalding hot, melting the combs, and letting every thing fall to the bottom in a sticky mush. Where you find such a condition of affairs in time, you may save the bees by rinsing them in water not too cold, and then drying them in the sun, placed on a coarse cloth or sieve, so the water will run off and allow them to get dry. When bees get smothered in this way they disgorge the honey in their sacks, and this is sufficient to make the whole mass about as wet as if they were drowned in honey. Sometimes a portion of the bees will escape, and cluster on the outside of the hive, as you suggest. We have sometimes saved these daubed bees by putting them in the upper story of a chaff hive, allowing the inmates to lick them off. By the time they get down to the entrance they will be all right; but if you let them loose when thus daubed they will crawl out in the dirt and die by the thousands.

CEMENT FOR BOTTOMS OF HIVES.

On page 502, June GLEANINGS, it is asked, "Will stone do for bottoms?" Yes, but cement ones are cheaper and better. Take cement, same as for cistern work. Make a mold of a size and shape that will take a wood bottom for Simplicity hive; fill with mortar and strike it off. This sets in a few minutes, and can be removed. I make the most of mine where I want them to remain. I make a little mound of dirt, sand, or sawdust, the height I desire my hive; level off the top a little larger than the bottom; have a frame about one inch thick, and the size I want my bottom inside. Set this on the mound, and fill with mortar, and press in the front, where you desire the entrance, with a suitable thin board; level with the top of the frame, then strike off and lift off your frame. It is cheap and durable—no rot, cracks, nor warp. No patent. They do well here. JOHN CRAYCRAFT.

Altoona, Orange Co., Fla.

TOBACCO COLUMN.

AT WORK ON COTTONWOOD.

I HAVE been reading in GLEANINGS where any one who would quit the use of tobacco you would send him a smoker. I have been using the filthy weed for 14 years, and I determine to quit it. I quit it May 15; and if I ever use the weed again I will send you one dollar for your trouble. I have 10 hives of bees, all in movable comb-frames, and they are at work on the cotton-blooms. I don't know whether cotton produces much honey or not. The honey-crop has been very poor in this section this year, but I think the

prospect is good for a fall crop of honey. Crops are fine in this locality. MOLLIE A. TAYLOR.
Ozen, Ark., Aug. 2, 1886.

HAS USED IT FOR 18 YEARS

I hereby say that I have quit the use of tobacco, after making myself a slave to it for 18 years. You will please send me a smoker, according to your agreement; and I pledge myself that, when I shall commence the use of tobacco I will forward the price of smoker to you. R. J. WEST.
Verona, Mo., Aug. 10, 1886.

I received the smoker all right, and am well pleased with it. I will endeavor to fulfill my contract with you. R. J. WEST.
Verona, Mo., Aug. 21, 1886.

I see that you give a smoker to all who will leave off using tobacco. If you will send me a smoker I agree to let tobacco alone; and if I take it up again I agree to send the pay for it. E. LADD.
Meredith Village, N. H., Aug. 11, 1886.

QUITS IT AT 45 YEARS OF AGE.

C. C. Lee requested me to say to you that he learned to use tobacco before he can remember, and has used it all his life. He is 45 years old. He says if you will send him a smoker (he has quit), if he ever uses any more tobacco he will pay you for it. W. D. TITCHENELL.
Pleasant Hill, West Va., Sept. 9, 1886.

I presumed that the promise to pay for the smoker upon becoming a smoker was implicit; in fact, a necessary inference, at all events. I consider myself bound in honor to pay for the same, accordingly to conditions named by you.
Woodstock, Ill., Aug. 8, 1886. A. W. CUMMINS.

DON'T CRAVE IT NOW.

You sent me a smoker when I quit the use of tobacco. I have never used it since, and I don't crave it now. It has been a great help to me. I have not been sick a minute since I quit the use of it. ROUSSEAU HURD.
Mt. Erie, Ill., July 20, 1886.

I have not used any tobacco since May 31, and have determined never to use any more. You may send me one of your smokers, if you see fit to do so; and should I ever use tobacco again I will send you the price of the smoker. MYRON I. NORTH.
Novesta, Mich., Aug. 18, 1886.

My neighbor has been induced to give up the use of tobacco, and requests me to ask you to send him a smoker. He promises to pay for the same if he ever uses tobacco again in any form.
San Augustine, Tex., July 30, 1886. D. W. MOSS.

A BETTER SUBSTITUTE FOR QUIETING BEES.

I see in your Tobacco Column you are giving smokers to encourage men to quit using tobacco. Now, I am a beginner in keeping bees, also in smoking. I am 36 years old, and never kept a pipe in my house until I thought I had to in order to sicken my bees; but it sickens me sometimes worse than it does the bees. If you send me a smoker I shall not be obliged to smoke with a pipe. I am well pleased with GLEANINGS and with the A B C book you sent me. I think no one keeping bees can afford to be without either. I would not take many times their cost and be without them.
Sandusky, N. Y., Aug. 21, 1886. R. G. LEWIS.

HAS GONE TO STAY.

I have given up tobacco, and it has gone to stay. Although I have never been a habitual user of the weed, I found that it was beginning to get the better of me, and, not desiring to become a slave to the vile stuff, I made up my mind that I would quit; and so, throwing away that filthy cigar, I said, "That's the last tobacco that shall go into my mouth, and I will keep my promise." Now, I don't want a smoker, but I should like to have the book entitled, "A Dose of Truth," which perhaps may help me along in this one good act of my life.
EMERY E. BENDERS.
Aspers, Adams Co., Pa., July, 1886.

Friend B., we notice you fought the battle with tobacco near the place where the battle of Gettysburg was fought.

FRIEND ERWIN TAKES THE PLEDGE, AND MORALIZES ON TOBACCO IN POETICAL MEASURE.

I just received your postal, requesting me to pay for the smoker if I ever use tobacco again. I promise to pay you for two smokers if I ever use tobacco again in my life. I took a pledge when I was a little boy about 8 years old, never to use intoxicating liquors as a beverage, and I have kept that pledge 42 years, and feel sure I can the rest of my days. I know I can do the same with tobacco.

That pernicious weed, whose scent the fair annoys,
Unfriendly to our highest joys;
Its worst effect is banishing for hours
The sex whose presence civilizes ours.
It is, indeed, the drug the gardener wants,
To poison vermin that infest his plants;
Are we to wit and beauty quite so blind
As to despise the glory of our kind,
And show the softest minds and fairest forms
As little mercy as the grubs and worms?

F. M. ERWIN.
Newhall, Los Angeles Co., Cal., Aug. 6, 1886.

KIND WORDS FROM OUR CUSTOMERS.

THE A B C.

The A B C of Bee Culture is at hand. I am delighted with it. It is rich with illustrations, and replete with interest. Every page is ablaze with inspiring thought. G. A. FARRAND.
Rockport, O., Sept. 18, 1886.

HOW OUR HIVE MATERIAL FITS.

If ever I had fun it was in putting those queen-hives together, which you made to order for me; every thing fits nicely. I believe I now have the very best queen-rearing hives in use.
Groesbeck, O. W. S. POUDER.

THE GRAMMAR CLASS IN BEE CULTURE.

I am very much pleased with Ernest. I believe if he lives he will be to the "grammar class" what his father has been to the A B C—viz., an honest, earnest guide. I like especially his style of dropping a word occasionally for his Master, and wish him the heartiest success. GEO. W. BLAKE.
Cape May City, N. J., Sept. 8, 1886.

[Thanks, friend B. Your kind words are not without encouragement. Yes, dear friend, I hope I shall ever try to drop a word for the Master.]

OUR UNTESTED QUEENS.

The tested queen you sent to me in June last is a prize to me. I would not take $25 for her and her colony. Her workers are of a beautiful bright yellow, very gentle, and as smart workers as I ever had in my apiary. They all show three bands distinctly, and that when they are entirely empty. I do not think they can be excelled by any.
Lonoke, Ark., Aug. 16, 1886. A. J. BLACKFORD.

REPORTS ENCOURAGING.

FROM 10 TO 19, AND 300 LBS. OF HONEY.

OUR bees have done well this summer. We increased from 10 to 19, and have taken nearly 300 lbs. of section honey, mostly white clover, and expect more. **FRANKLIN FICKES.**

Blackleysville, Ohio. Sept. 6, 1886.

My bees have been swarming all summer, and now honey is coming in with a rush. **J. C. MERRIMAN.**

Deckersville, Mich., Aug. 7, 1886.

HONEY-CROP LIGHT.

The honey-crop is light in this section. I shall have only about six tons; ordinarily I should have fifteen. I am holding it for better prices, which are sure to come. **S. Z. MILLARD.**

Banning, Cal., Aug. 28, 1886.

I have 30 swarms of bees, mostly black bees, a few hybrids; some of my swarms have given me 80 lbs. of fine box honey to a colony, and two new swarms. **BENJ. OLLERENSHAW.**

Lima, N. Y., Sept. 2, 1886.

A GOOD SEASON.

We have had a very good season so far—plenty of rain all summer, and bees have done well on white clover and blue thistle. If they had all been in good shape in the spring we could easily have made 100 lbs. of comb honey per colony; but as it is, some will exceed 100 lbs., while all will average over 50 lbs., spring count. The honey is of nice quality. **H. W. BASS.**

Happy Creek, Warren Co., Va.. Aug. 9, 1886.

FROM 84 TO 125, AND 5000 LBS. OF HONEY.

We are having a terrible drought here at present, not having had sufficient rain to do much good since the fore part of May. However, the bees have done remarkably well, and bee men have no reason to complain, except at the low price of honey, which is retailing at 12½ cts. for comb in 1-lb. sections, and 8⅓ for extracted. My report is as follows: 84 colonies, spring count; increased by natural swarming and building up nuclei, to 125; took 3000 lbs. of extracted, and 2000 lbs. of comb honey in sections. Bees are in good condition now.

Oskaloosa, Ia., Aug. 27, 1886. **S. L. SHERMAN.**

FROM 24 TO 40, AND 3700 LBS. OF HONEY; FIRST PREMIUM ON HONEY, A LA A B C.

I began the season with 24 stands, about 20 of them strong. I increased by natural swarming to 40 stands, and took 2300 lbs. of honey, 1700 lbs. of which was comb honey, mostly in 1-lb. sections. I use the "Langstroth-Simplicity" hive, and think it can't be surpassed for taking comb honey in 1-lb. sections. This has been a splendid season, both for quality and quantity of the honey-crop. The bees had a long run on white clover and a short but heavy run on basswood. Since basswood ceased, my bees have gathered enough fall honey to put them in splendid shape for winter. I got the first premium on both comb and extracted honey at our county fair this fall, the result of knowing how to take comb honey in nice shape, which I learned from the A B C book and GLEANINGS.

Browntown, Wis., Sept. 16, 1886. **HARRY LATHROP,**

NOTES AND QUERIES.

REARING QUEENS IN GREENHOUSES.

ABOUT those bees in greenhouses, to make cucumbers bear, don't you think that is the place to breed queens and mate them? **A. W. DENNISON.**

Sherburne, N. Y., Sept. 24, 1886.

[Friend D., the idea was talked about a good many years ago, and considerable experimenting was done in trying to get queens fertilized in wire-cloth houses and in greenhouses; but it all resulted in failure, although a great deal of money was expended in the matter. With the bees working as naturally as they do in friend Rawson's cucumber greenhouses, very likely it might be done, but I hardly think it would succeed, even then, enough to make it practicable. If the colonies in the greenhouse are fed up to the swarming-point, so as to make the hive produce drones, perhaps it could be managed.]

GROWING SWEET CLOVER SUCCESSFULLY.

I sowed five acres more of sweet clover this year. I was surprised to hear that Dr. Miller could not get a stand of it. I have no trouble at all in getting it to grow. In the fall is the best time to sow it.

Hillsdale, Ia. **E. W. PITZER.**

HONEY SEASON ABOUT OVER.

Coreopsis, Spanish needle, did not yield abundantly, on account of dry weather. I realized about 50 lbs. per colony, and have a little to extract yet. There will probably be 8 or 10 lbs. more.

Iola, Ills., Sept. 18, 1886. **GEO. WISEHEART.**

HONEY ICE-CREAM.

I made it last year for the State Fair, and it took well. Now I regularly keep it in my store, and it is much liked, and sells. It is simply using the finest white-clover honey for flavoring, and not getting it *too sweet*. This is another avenue to dispose of honey; it is only a little, but the little helps. **ARTHUR TODD.**

Germantown Ave., Philadelphia, Pa.

A POOR SEASON.

The honey season has been a poor one in this locality this year. I commenced the season with 86 good strong colonies, and have taken 1000 lbs. of comb honey and 900 lbs. of extracted, and increased to 125 colonies. I shall have to feed some, as the bees did not fill up from basswood. This is not a very good report, but it is the best I can do this year. **B. B. WESLEY.**

La Grange, Lorain Co., O., Sept. 14, 1885.

EGGS FAILING TO HATCH.

We have in appearance a very fine queen, a daughter of the one we purchased of you. She was reared in a two-frame nucleus, July 12 being the day of her birth. She now has five frames, mostly filled with eggs; some were laid fourteen days ago, and we have failed yet to see the first egg hatch. Will you kindly inform us what the trouble is? **A. E. HARKER & BROS.**

Hornerstown, N. J., Aug. 4, 1886.

[I can not tell you *what* the trouble is, friend H., but I can explain that the phenomenon is not new. Perhaps one queen in five or ten thousand will lay eggs that never produce larvæ, like the one you have. It is simply an accidental physical defect.]

CANADA THISTLES, AND HOW ERADICATED.

In regard to Canada thistles, I got the best of a patch about 10 by 12 feet by pulling them up just after a rain. It was rough on the thumb and finger, but I cleaned them, and there has not one shown itself for two years now. I pulled some with roots two feet long. ED. H. BAGGALEY, 13—39.

Weston, O., July 19, 1886.

[Friend B., I am pleased to tell you that I have also got ahead of the Canada thistles on our little patch; at least, they are getting to be scarcer and scarcer, and now they have almost ceased to sprout. My plan is to dig the ground over with my fingers about once in three days. From this repeated digging, it has now become so fine that it is just fun to hunt it over for the smallest sprout. I hardly think it will manifest itself at all another season. On a large scale, I would use an Acme harrow.]

CAN WE PRESERVE THE AROMA OF NEW HONEY?

Is there any method by which the aroma of freshly extracted honey can be secured to the honey during the year? Will fruit-jars sealed do it?

St. Paul, Minn. WM. WAKEFIELD.

[Yes, my friend, sealing it up as soon as it is gathered will do it, providing the honey is not so thin that it soon sours; but, by the way, I think I would rather have it after the aroma had some of it departed—basswood honey, for instance; or, if you please, honey from seed onions.]

NOT A SMELL OF BASSWOOD.

There was not basswood honey enough this year to give me a smell of it. Last year it seemed to be as abundant as white clover. Bees have gathered more than usual from buckwheat, and will get some from goldenrod; but we do not count much on this for surplus. J. L. HUBBARD.

Walpole, N. H., Aug. 23, 1886.

DROUGHT AND BUG-JUICE.

Inclosed find one dollar, to pay for GLEANINGS another year. I did not make this dollar from the bees. Drought and bug-juice are responsible for it. I increased by natural and artificial swarming from four to twelve. All are very strong but three. I have taken but about 50 lbs. of comb honey.

Bloomingburg, O., Aug. 14, 1886. DAVID LONG.

PURE ITALIANS AHEAD OF HYBRIDS AND BLACKS.

My report for this year is, with the majority, very short. Spring count, 20; one weak; increased naturally to 38. I have taken about 300 lbs., mostly extracted. It has been a very poor year for honey, and a large number have lost all or nearly all their bees. I had to double back to 33 stands, which I hope to winter without feeding. My pure Italians beat both hybrids and blacks, they having gathered all the surplus I had. C. E. JENKINS, 20—33.

Bryan, Texas, Aug. 23, 1886.

THE INTENSIVE SYSTEM.

Nine years ago I started in the bee-business; those nine years have been years of pleasantness, and I think I have succeeded nicely. I have 50 strong colonies and 60 nuclei, and that is as many as I care to keep, as I run them on the "Intensive System;" that is, the greatest possible gains with the facilities afforded. The phrase, "Intensive System," I learned from Rev. Sam Jones, but I believe it is orignal with me when applied to bee-keeping. WALTER S. POUDER.

Groesbeck, Ham. Co., O., Sept. 13, 1836.

MOTH, AND HOW TO GET RID OF THEM.

The best moth-trap that I have ever heard of is this: Take the refuse, after rendering combs, and keep in a box or bee-hive in the apiary, and the millers will congregate on the chunks of refuse and deposit their eggs; and by looking over the refuse every morning the bee-keeper can destroy lots of millers. Of course, the best protection to combs is a strong colony of bees; but nuclei have to be protected, and I find it pays to destroy all the millers I can. J. B. RAPP.

Owensville, O., Sept. 1, 1886.

[The Italians are the best moth-traps we know of. In our apiary, exclusively Italians, we have never been troubled with moth.]

A CORRECTION.

I notice just one typographical error in my article of the 15th of Aug. The word "boiled," 2d line, 2d column, page 644, should be "bolted."

London, England, Sept. 6, 1886. S. CORNEIL.

OUR OWN APIARY.

DOMESTICATING BUMBLE-BEES.

LAST week, as I was passing through the apiary my attention was arrested by the apiarist calling to me something in this wise: "Ernest! Ernest! hello there!"

"Well," said I, "what'll you have?"

So saying I peered this way and that through the long rows of grapevines shading the hives. Finally, through the leafy avenues I espied a hat whose owner, as he neared me, called out, "Just come here a minute." I followed, morally certain that he had found a hive badly infected, or that a colony was doing some unaccountable thing which he could not explain. We halted in front of a Simplicity bottom-board, from which the hive-body had been removed. Nothing very peculiar about that bottom-board, thought I, while with the smoker, in the meantime, the apiarist gave a few puffs under it. This done he slowly lifted one edge of the board.

"*Apis Americana* (?), and successfully domesticated too," said I, as the apiarist pulled the straw over and handed me a few cells of honey.

Perhaps from an enumeration of some of the characteristic qualities of these bees, some of our hay-making juvenile friends may recognize the species. They are a large bee, as large as acorns, and in color not unlike Carniolans—distant cousins, may be, though I will not say positively. Their numbers vary from one to three dozen. Strangest of all, their surplus honey is stored below, and their brood is above. They are very peaceable when handled with smoke, as we had no trouble with them; but when handled with paddles in youthful hands, small boys are loth to call them any thing else than terrors—at least, that was formerly my verdict against them. Their honey is delicious—at least, so says the editor of GLEANINGS. I have often heard my schoolboy friends pronounce bumble-bee honey superior to any thing else. These bumble-bees can be handled with smoke as readily as the Italians. In fact, we take pleasure in showing them to visitors and others. They neither have stung nor have offered to sting; in fact, I think if the juveniles manage it rightly they can handle them like kittens.

I mention these facts to show what may be done with these clumsy lovers of sweets, and perhaps our juvenile friends and others may be interested enough in their peculiar habits to give them a trial —not that they will yield any large returns in honey, for the comparative amount of honey stored by them is very small. Our bumble-bees have stored, I should think, a little over a pound of honey, all told. As the bees themselves die off on the approach of winter, and their queen "hibernates," they gather only enough to supply present needs.

IGNITING FUEL IN SMOKERS.

On page 723 our friend J. A. Green tells how to light the fuel in smokers by means of a common oiler filled with kerosene. Of course, I *knew* it would work, but I always like to try a thing, nevertheless. I took one of our oilers from the ten-cent counter and filled it as directed. I then prepared my Clark smoker, as described in this department of the previous issue. This done I sent a couple of squirts from the oiler on the fuel, and dropped in a lighted match. I hardly need tell you that I had some hot coals in a twinkling; and what a smudge when I filled the fire-box level full with sawdust! How simple! and why did we never think of it before? No, brother bee-keepers, if you once light your smoker in this way I think you will never have occasion again to fuss with your wife's kitchen stove for a "few coals." Although I have had good success igniting the fuel in my smoker with a match and fine fuel as I have before described, I think I shall hereafter use the oiler. Why? Because it is much the quickest way I know of; and, second, it is a matter of little consequence whether the rotten wood be dry, finely pulverized, or coarse, the oil will quickly convert them into hot coals. The sawdust or shavings can then be dumped in without fear of putting out the fire.

THE IMPORTANCE OF GIVING YOUR OWN PERSONAL ATTENTION TO YOUR APIARY.

I have been waiting for two or three days for an opportunity of carefully examining personally the colonies in the apiary, but it has rained and still rains (the equinox is at hand). In regard to personally examing the hives, I would say that you may have an apiarist ever so careful, yet, as I have learned from experience, it is well to review his work. One or two instances will illustrate:

The last time going through the apiary I discovered that the frames were spaced too far apart in anticipation of winter; but at this particular time red-clover honey was coming in quite freely. The consequence was, many of the combs were bulged out of proportion; brace-combs were built in between, and in one or two instances there were newly built pieces of comb with brood in. As the apiarist had not anticipated such a heavy flow of honey at that time (about Sept. 12th), he had so spaced the combs. He should have waited until he was ready to pack the colonies in chaff. Again, in going about half way through the apiary I had found five or six cases of foul brood, when the apiarist had, only a day or so before, discovered but one in the whole apiary. I do not attribute this difference to any skill of my own, but I *did* feel as if the whole trade in bees and queens during the next and following seasons depended upon how *thoroughly* I did my work, and that if a *single* case of foul brood escaped my notice there would be no use trying. Realizing this I not only examined one frame but every frame. If I could not detect the familiar odor of foul brood I did not then feel satisfied of its absence, but opened any cells of doubtful appearance, and in this way in two or three instances I found diseased cells. Had I depended upon the odor or the general appearance of the combs, I should have pronounced a few colonies perfectly healthy when they were in reality actually diseased.

I do not wish it understood, in going thus into details, that I take this opportunity to criticise the manner in which our apiarist has done his work, for in many things he has shown himself *very* careful, but to illustrate the importance of going over the work yourself. The trouble was, the apiarist did not realize, and, indeed, perhaps could not *feel*, the supreme importance of handling foul brood thoroughly, as I did. I well recollect, when I first began handling bees, some eight or ten years ago, how father used to "lecture" me on doing things in the apiary just *so*. He would review my work, and, if carelessly done, I *heard* from him. Although I sometimes felt discouraged, that sort of rigid tutorship did me good, and made me to feel that handling bees is not play, but that it is a trade, and as such it should be thoroughly learned. ERNEST.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, O.

TERMS: $1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, OCT. 1, 1886.

Hold thou me up, and I shall be safe.—Ps. 119: 117.

WE are pleased to inform our friends that our subscription-list is still running up. Up to date we have 5904, nearly 6000. Many thanks for your patronage.

NEW GARDEN SEEDS.

SEVERAL of the friends have been wanting to know when we should have new seeds to send out. Well, we have already new seed of Boston market lettuce from selected heads, and Chartier radish.

FOUL BROOD AND CANADA THISTLES.

BOTH are killed out, so far as we can discover at the present writing. We are, however, on the alert; and just the minute we can detect the presence of either we are going to stamp every trace of it out of existence.

CURTAILING CONTRIBUTIONS.

As a rule, we prefer to put in every article as it is received, entire; but where a contributor gets into a habit of being too lengthy, or, in fact, where he seems to threaten to take so much space that other good men can not be heard from, we have no other way to do than to cut his article down; and we shall do this, even if he be the best writer we have.

TO PRESERVE GRAPES WITH HONEY.

OUR friend Mrs. Axtell, of Roseville, Ills., sends us the following clipping from the *Iowa Homestead* in regard to the subject:

> Take seven pounds of sound grapes on the stems, the branches as perfect as possible, and pack them snugly, without breaking, in a stone jar. Make a syrup of four pounds of honey and one pint of vinegar, with cloves and cinnamon to suit (about 3 ounces of each is the rule). Boil them well together for twenty minutes; skim well, then turn, boiling hot, over the grapes, and seal immediately. They will keep for years, if you wish, and are exceedingly nice. Apples, peaches, and plums may be done in this way.

PEACE AND PLENTY.

As a rule, I believe we are as a nation blessed with an abundance of almost every thing; and whatever you need to buy can generally be procured in good quality and quantity for a small amount of money. While this is a little hard on producers, it is, on the other hand, a blessing to the purchaser. Please let us remember this when we are inclined to think we have to work hard for tolerably small pay.

A 40-HORSE-POWER ENGINE FOR SALE CHEAP.

SEPT. 29.—Our new automatic cut-off 90-horse-power engine has just been started to-day, and is ready to drive the machinery in all our buildings. This is the Buckeye engine, built at Salem, O., the engine which won gold medals at the Centennial, the New Orleans, and the Cincinnati Expositions. Now, we want to dispose of our 40-horse-power engine which has done such faithful work for us for the last eight years. It is a standard plain engine, Lord & Bowler make, 12×20, with a 9-foot balance-wheel and a 6 foot fly-wheel. We will offer it, put in good repairs, for $350.00. We will throw in the stone upon which the bed-plate is bolted, free of charge. For further particulars, write us. Whom shall we hear from first?

TRAINING GRAPEVINES OVER BEE-HIVES.

OUR 500 Concords that shade our bee-hives are just now giving the finest and largest crop of grapes they ever produced. Many single vines fill a ten-pound basket of great heavy handsome clusters. As there are about 500 vines, you can believe the apiary presents a beautiful appearance. I tell you, it is real fun to go out and show folks the bee-hives and then pass around the fruit. Almost every visitor exclaims, "Why, how is it that your bees do not eat the grapes?" Well, it is a little funny, but not a bee is to be seen on any one of the thousand bunches of fruit that hang right over their hives. But when we gather baskets of grapes, and put them out in front of the store, waiting for customers, the bees just make a regular raid on them. Do you see why? Why, it is very simple. The grapes are so ripe that it is almost impossible to pick them and lay them in baskets without bruising or bursting more or less of the berries. The bees then have a regular picnic sucking out the juices. If you think the plan of training Concord grapevines in front of bee-hives, as laid down in the A B C book, is all "on paper," as one or two friends have expressed it, just pay us a visit now. We are getting 3 cts. per lb., or 2½ cts. for 10 lbs. or over; 100 lbs. or over, 2 cts. per lb.

DIGGING POTATOES AT THE RATE OF A BUSHEL IN SIX MINUTES.

I HAPPENED to be down at the creek bottom where one of our men was digging "Dakota Red" potatoes. The crop was raised according to Terry's instructions. A man was throwing them out with a potato-fork, and a small boy was throwing them into one of our bushel boxes. I thought they were making pretty good progress, so I glanced at my Waterbury watch, and, to my astonishment, a good plump bushel was thrown out and picked up in just six minutes. The man's wages is 15 cts. per hour, and the boy's 5 cts., so you can see it cost me just two cents a bushel to dig the potatoes and put them in the boxes. I do not know what the cultivation cost, but the ground is so nice and mellow that it did not cost very much. Now, there are other places on our ground where the man and boy would do well if they got a bushel in a whole hour. Do you see the point? Poor ground can be made, by proper care, to do as well as the best; and you have to go through all the motions with a poor crop, almost, that you do with a good one.

THE HEN THAT ALWAYS LAYS EGGS.

IT is the same hen I have told you about, friends—the cross between the Plymouth Rock and Brown Leghorn. She commenced to lay in February, and is still laying during these last days of September. Now, I want to ask the poultry-friends, Why not breed from such fowls as these, rather than from those that show more or less of the "100 points" as a standard of excellence? I have looked the poultry-journals over, to see if I could find any one who has bred for eggs, without regard to any other qualities. Why, it seems to me I could almost afford to give a thousand dollars for a thousand hens that would do as well as this one. You may ask, Why not do the same thing with bees? That is it, exactly. Why not give our strength and energies to the production of *bees* that gather *honey*, and *fowls* that lay *eggs?*

LETTUCE FOR POULTRY.

IT seems to me a little singular that our poultry-journals do not have more to say on the above subject. We had just started a fine plat of lettuce, which we expected to head up about Thanksgiving time; but that brood of thirteen Brahmas we told you about went for it with such greed there would hardly have been a leaf left in 24 hours. We tried giving them corn, wheat, mashed potatoes, and other things; but, no, they considered thrifty rank-growing lettuce leaves a good deal better than any of it. Finally we transported the brood down to the carp-pond; but they found another lot of lettuce down near the creek bottom, and began paying their respects to that. This latter patch was, however, so large and thrifty we thought it would grow as fast as they could consume it; but I tell you, 15 or 20 half-grown Brahmas will consume a pile of lettuce. Now, then, why not let them have it? Lettuce-seed scattered where we have dug potatoes, or taken up some other crop, will make an amazingly rapid growth in the fall, and it does not cost any thing of any account, except the seed. Some good old stable manure raked in with the soil will help the lettuce amazingly. Cabbage and lettuce will often start hens to laying when they will not lay otherwise. We have quite a quantity of Hanson lettuce-seed that we will send by mail at 10 cts. per ounce, for the above purpose, if you don't happen to have seed of your own. The seed is three or four years old, but it germinates beautifully, and pleases the Brahmas, I tell you.

DAIRYMEN!

For only $1 and this adv't we will send the **Dairy World,** best and largest dairy journal published, (price $1) one year; one **Sumner Cream Tester,** price $1, for testing milk of 6 cows at one milking; one **Perfect Milking Tube,** price 50c, for cows with sore or obstructed teats; one **Hazard's Butter Making,** a guide to good dairying, price 25c—all for $1. Address THE DAIRY WORLD, 61 LaSalle St., Chicago, Ill. Samples free.

350 acres good table land, ½ cleared and in a good state of cultivation; the rest tolerably well timbered; finely situated for stock, fruit, or grain farming; an abundance of fruit and good spring water; good house with 9 rooms, garret and cellar, a large barn, and other necessary buildings. Price $7000.

Also 500 acres adjoining the above, 50 acres cleared, a log house and stable, some fruit, 200 acres of mountain land; the rest nice for farming. Price $3000. Either farm will divide well, and is a good site for an apiary. For particulars address

PREPARE FOR WINTER.

We have unequaled facilities for manufacturing the Root chaff hive at a great reduction from ruling prices. Mr. Zeno Doty, Grafton, Neb., writes July 9th, "Your material, make, and price is far better than I can get anywhere else." Send for price list and special prices for this fall. 16tfdb
A. F. STAUFFER & CO., Sterling, Ills.

GOODS NEAR YOUR HOME, AT A REDUCTION FROM REGULAR PRICE.

We have the following lot of goods at the places named, for which we want customers. Now, it is altogether likely that there is some one located not very far from where these goods are who will be needing just such articles, especially if he can get them a little lower than the regular price, and doesn't have to pay much freight charges on them. In hopes that there are such persons, we append a list of the articles for sale, giving the present value of the goods and the amount we will take for each lot entire. We give a number to each lot, and the name of the place where they are being held, subject to our order. Remember they are all perfect goods, just as fresh and new as if shipped from here. Remember, also, that at the price we offer them we can not break lots; each lot must go entire. In making your orders, please give the number of the lot as well as the articles contained in it, and thus help us to avoid mistakes.

No. 1. Aplington, Iowa.
Ten 2-story portico hives, complete, in flat, for comb honey, including m. c. frames, wide frames, sections, separators, thin fdn. for sec., 7 lbs. brood fdn., and enamel sheets. The lot foots up to $25.30. We will sell it complete for $22.00

No. 2. Union City, Ind.
13 combined shipping and honey crates flat; 90 tin separators for above crates; 26 pieces glass for above crates; 40 metal-cornered brood-frames in flat. Present value, $4.50; will sell for 4.00

No. 7. Nassau, N. Y.
200 wide frames, for 8 1-lb. sections, in flat. Worth $4.00; will sell for 3.75

No. 8. Riverside, N. J.
500 1-lb. 7-to-foot sections. Worth $2 00; will sell for .. 1.75

No. 9. North Walton, N. Y.
100 metal-cornered frames, in flat. Present value, $2.50; will sell for 2 50

No. 12. Caribou, Maine.
900 sections, 4¼ x 5 x 1 7/16 wide, open on all four sides. Present value, $4.50; will sell for 3.50

No. 14. Delaware, Ohio.
35 bottom-boards for Simp. hives; 210 tin separators for combined crates. Present value, $8 75; will sell for 7.50

No. 15 Foster Brook, Pa.
100 wired m. c. brood-frames, in flat, including wire and tin bars. Present value, $3 00; will sell for 2.75

No. 16. Johnson City, Tenn.
One No. 7 honey-extractor, with basket, only 15 in. deep. Present price, $8.00; will sell for 6 00

No. 17. Cairo, W. Va.
One 2 story Simp. hive, rigged complete for comb honey, and 5 lbs. fdn., ½ thin, for sections, and ½ for L. frames. Present value, $5.25; will sell for 4.75

No. 18. Elmira, N. Y.
One 2-H. P. engine and boiler complete. This has been used some, but has been put in as good shape as when new. Price of a new one, $175.00; will sell this for $150.00

No. 19. La Salle, Ill.
6-in. foundation mill. Present value $13.50; will sell for 11.50

A. I. ROOT, Medina, Ohio.

LARGEST BEE-HIVE AND SECTION FACTORY IN THE WORLD.

GREAT REDUCTION!

HONEY COLUMN.

CITY MARKETS.

CINCINNATI.—*Honey.*—There is a fair demand for choice comb honey in 1 and 2 lb. sections, which brings 12@15c a lb. in a jobbing way, according to quality and neatness of package. There is also a fair retail and jobbing demand for extracted honey in square glass jars for table use, while the order trade for dark grades from manufacturers is improving. We quote extracted honey at 3½@7c on arrival, according to quality. *Beeswax* is in good demand, and good yellow brings readily 20c on arrival.

CHAS. F. MUTH & SON,
Oct. 9, 1886. Cincinnati, Ohio.

MILWAUKEE.—*Honey.*—The market for choice comb and extracted honey is firmer, and I am trying to establish a little higher range of values. I will quote 1-lb. sections, white, 12½@13c; 2-lb. sections, white, 11@12c. Dark, not wanted. Extracted, white, in kegs and ½ bbls., 6½@7; same, in tin, 7@7½; same in bbls., as to quality, 5@5½.
Beeswax, quiet.

A. V. BISHOP,
Oct. 2, 1886. 142 W. Water St., Milwaukee, Wis.

BOSTON.—*Honey.*—We report good sales at 14@16c for fancy 1-lb. comb; 12½@14c for fancy 2-lb. comb.

Oct. 12, 1886. BLAKE & RIPLEY,
57 Chatham St., Boston, Mass.

CHICAGO.—*Honey.*—The demand for honey is better, with prices unchanged from last quotations. Receipts are quite large, both of comb and extracted. *Beeswax*, 23@25c. A majority of all consignments of comb honey is of excellent quality.

Oct. 7, 1886. R. A. BURNETT,
161 So. Water St., Chicago, Ill.

CLEVELAND.—*Honey.*—There is no change in price; let former quotations remain. A. C. KENDEL,
Oct. 7, 1886. 115 Ontario St., Cleveland, O.

DETROIT.—*Honey.*—There is a good supply of comb honey in the commission houses, put up in every conceivable shape, a large proportion just as it came from the hives. Buyers sort it over and take the most attractive first. Prices remain the same; viz., from 12@13c for the best. Dark, 10@11c.
Beeswax, 23c.

M. H. HUNT,
Oct. 10, 1886. Bell Branch, Mich.

FOR SALE.—1200 lbs. of basswood and aster honey for sale at 5¾c per lb., put up in 15-gallon kegs. Sample sent on application. W. A. COMPTON,
Lynnville, Tenn.

1880.—NOTES FROM THE BRIGHT-BAND APIARY.—1886.

NO FOUL BROOD.

Friends:—I want your patronage. I can ship pure Italian queens by return mail; my stock can not be excelled, and I devote my whole time to rearing queens, and will fill your orders with my own hands. Satisfaction guaranteed. One untested queen for 80 cts.; two, $1.50; or any larger number at 70 cts. each. Send for circular on the "Coming Bee."

HERE IS YOUR CHANCE!

Will deliver on board cars at Shreveport, La., full colonies of bees with untested queen, for $3.25 each (9 frames). Make P. O. orders payable at Shreveport, La., and address your orders to

CHAS. KINGSLEY,
Benton, Bossier Parish, La.

SAY, LOOK HERE! if you want something that will hold all sorts of small things, as papers, almanacs, letters, magazines, cards, etc., and do it quick, before it gets lost or blown away, or the baby tears it, send 10c. for an **Acme Paper-Holder;** two, 15c.; five, 25c.; twelve, 50c. Agents wanted. Address **N. E. JOHNSON, Medina, O.**

REDUCED!

BEE-KEEPERS' MAGAZINE

TO

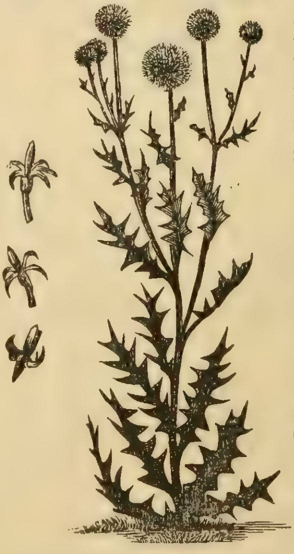
25 Cents Per Year.

FROM JANUARY FIRST, 1887.

SAMPLE COPY FREE.

20-1db **BARRYTOWN, N. Y.**

The Chapman Honey-Plant.



In accordance with a previous notice in bee-periodicals, I am now prepared to fill orders for the seed of the above plant at the following prices: ½ oz., $1; 1 oz., $2; 2 oz., $3; 4 oz., $5; ½ lb., $8. One oz. contains from 1600 to 1800 seeds. On account of extreme drought my stock of seed is limited, and persons ordering will be served in rotation. The seed should be sown in the early spring, and general directions for cultivation will be given on each package.

This plant is not an obnoxious weed, and is as easily eradicated as clover. Having carefully watched its habits of growth, and its honey-producing qualities for the past six years, I believe those who commence its cultivation in a liberal way will be better pleased than by commencing with a small quantity of seed. It has been tested by prominent bee-keepers all the way from Vermont to Nebraska and Ontario. We refer to the report of the committee appointed by the North-American Bee-Keepers' Association held at Detroit in 1885. The committee reported at the Indianapolis, Ind., convention held Oct. 12th to 14th, and their report will be found in all bee-periodicals publishing the report of that convention.

Write all orders plainly, and give your postoffice address in full.

H. CHAPMAN,
Versailles, Cattaraugus Co., N. Y.

40-Horse-Power Engine for Sale.

Our new automatic cut-off 90 horse-power engine is now driving the machinery in all our buildings. Now, we want to dispose of our old 40-horse-power engine which has done such faithful work for us for the last eight years. It is a standard plain engine, Lord & Bowler make, 12x20, with a 9-foot balance-wheel and a 6-foot fly-wheel. We will offer it, put in good repairs, for $350.00. We will throw in the stone upon which the bed-plate is bolted, free of charge. For further particulars, write us. Whom shall we hear from first?

A. I. ROOT, Medina, Ohio.

GLEANINGS IN BEE CULTURE.

DEVOTED TO BEES, HONEY, & HOME INTERESTS.

Vol. XIV. **OCT. 15, 1886.** **No. 20.**

TERMS: $1.00 PER ANNUM, IN ADVANCE; 2 Copies for $1.90; 3 for $2.75; 5 for $4.00; 10 or more, 75 cts. each. Single Number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent TO ONE POSTOFFICE.

Established in 1873.
PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

MRS. CHADDOCK'S VIEWS ON BEE-PASTURAGE.

THE STUDENT BUSINESS.

WHEN I began to keep bees I did it with the *distinct* understanding *with myself* that I would never sow a seed of any kind to raise pasturage for bees. I said, "If bees don't pay with what nature furnishes them, then I won't keep bees." So in reading GLEANINGS and the other journals, when I come to an article about any kind of bee-pasture I *skip it.* When I received the A B C book I read almost every thing in it. I do not remember now, but I suppose I skipped all the bee-pasture in that too.

Last week I took a notion to raise some alsike clover, if I can be convinced that it is as good a hay crop as red clover. Mr. Chaddock is willing to sow an acre; but what is *one acre?* I want 20 acres, and I am trying to persuade the farmers near me to sow some of it. I will give them the seed. If it only blooms at the same time that the white clover does, it will be hardly worth while to sow it, for there are not half bees enough around here to gather the white-clover honey. If the first crop is cut while in blossom, what is to hinder the second crop from bearing seed? If alsike is no better for honey than buckwheat is here, then it is useless to sow it for the bees. There has been no honey, to amount to any thing, in the buckwheat around here, more than once in ten years.

HOW MRS. CHADDOCK GOT INTO THE STUDENT BUSINESS.

You ask how I came to go into the "student business." I did not *go* into it; it came upon me, just as other people are afflicted with boils and carbuncles. You know—or, rather, you don't know, that I have a few dozen nieces and a few score of cousins, and several hundred young woman-friends, besides my own daughters, who are always coming to me for advice and help. They all learned, a good while ago, that I was fond of giving advice, and I think they come to me a good many times to tell their troubles when they care not a whit about the advice. They want some one to talk it over with, and so they come to me. They are nearly all "school-marms;" a few are dressmakers, and one or two of them work out. One of the fairest and best of them all is "my student." She is a "school-marm," and a good one. She can earn from $25 to $40 a month teaching, and she likes it. But every once in a while (generally during vacation), she takes a notion to clerk in a store, or be a milliner, a farmer, or something. This vacation she is going to be a bee-keeper. She wears long dresses that touch the ground all around, and has her bangs done up most of the time. She has white dresses to wash every week, and six white skirts. I do not believe she is in earnest; and if she were she has no time for it. That is the reason I do not want to bother with her. But over yonder at the back of our fields lives Mollyony Johnson. She is a Swede girl, 18 years old. She is a little round-shouldered, has red hair, and great big freckles. She is a good girl, and I like her; and if she wanted to stay with me and learn bee-keeping I would take her gladly. She is always laughing; and when she goes to wash the windows she says, "I don't think so I can do it good," but she always *does* do it "good." She doesn't scream when a bee stings her, nor run from snakes, nor wear bangs. I like Mollyony for every-day wear better than I do the "school marm;" though the "school-marm" is bright and smart, and I like her too.

As to hiring out to drive that mule team, I never offered to work for my board in warm weather; I think I am worth more than that. But every winter I am frozen up, and as soon as I begin to house up I get sick and stay sick till warm weather comes. Last fall I made up my mind to go to Florida to spend the winter, if I could find something to do to pay my board while there. I want to be outdoors, and I want to be doing something.

Mahala B. Chaddock.

Vermont, Ill., Aug. 4, 1886.

Mrs. C., I was a little afraid you were a little inclined to be uncharitable toward the "school-marm;" therefore I was very glad to hear you say, toward the conclusion, that you liked her too. These friends of ours have different talents, different capabilities, different missions in life, and very likely they are all lovable, if we come to understand them; and this we can do only by becoming intimately acquainted. And this brings me to my latest hobby, of making it a point to get *acquainted* with people; then you know we shall come nearest to that happy state of loving everybody. Is it not so?

MEDICINE VERSUS HYGIENE.

SOME SENSIBLE IDEAS FROM FRIEND TERRY.

FRIEND ROOT:—On page 773 of Gleanings you give us a very interesting talk in regard to dosing with plants and herbs. I agree with you fully; and if we could get every one else to agree with us, we might do much good. The quantities of medicine given in many families is appalling. Surely a magazine devoted in part to "home interests" can not do better than to protest against this but too common practice of dosing ourselves, or the children, for every little ailment, even with home-made remedies. Then look at the thousands of tons of patent medicines that are sold every year, and, of course, swallowed by some one. Why, only the other day I called on one of the most intelligent men in our town, and found him opening a bottle of patent medicine. His excuse was, "I have been rather out of sorts for some days, and need something to tone me up."

Ever since the writer was old enough to know any thing he has been down on this dosing business, although every rafter in the old garret used to be hung full of dried herbs of every description, decoctions from which were often put on, or into, the other children. Once when I was quite poorly father called in a celebrated physician, author of a work on family dosing. He said I was "bilious," and left a box of pills for me. I was only eight years old; but I had a great horror of pills. Mother fixed one up in a spoonful of sauce and brought it to me. I couldn't and wouldn't take it. Then they dissolved it in water, and tried to make me drink it. At last they offered me a $5.00 gold-piece if I would take it, but I wouldn't. Worried out I finally told them to put it in a raisin and I would try it. I took it in my mouth; and as mother turned to put the spoon on the table the pill went out the open window. Next morning the doctor called. "Why," he says, "he is much better. How beautifully these pills do work! Give another to night, and he will be all right in a day or two." The second one followed the first, and I got well rapidly. It was ten years before I dared tell the story; but meanwhile no pills went down my throat.

Our best physicians now give but little medicine. They know that pure air and sunshine, proper food and exercise, are the best medicines, as a rule. It was a wise man, but rather ahead of the times, who wrote some 30 years ago, that "doctors do precious little when they don't do harm."

Some years ago the writer was laid up by a very badly injured foot. He even got so low that there was a slim chance of his ever being any better. People would come in and say, "Why don't you try this or that? The doctor isn't doing any thing for you." So I asked him one morning if there wasn't something known to science that would help my foot to heal up? He replied, "I am sorry to say that there is not. We can only keep it wet with carbolic acid, and let nature work." I knew he told the truth, and was satisfied. With some natures, perhaps, a harmless substance, put on with strong assurance that it would surely cure, would have been best, so strong an influence has the mind on the body, hence our often wonderful so-called "faith cures." My doctor knew me, and knew that the exact truth was what I wanted, although it was a sad admission for science to make, in view of all the healing (?) salves and ointments that our mothers used to have.

I remember once taking a very hard cold. It made me very sick, and wife sent for the same physician. He came and looked me over and said, "Keep covered up warm in bed, so warm as to be rather uncomfortable, and you will be all right in a day or two." Not much medicine for $2.00, surely; but it proved to be all I needed. In some places, I presume, he would have given some bread pills or sweetened water, "a teaspoonful every other hour." Now, this man is thoroughly posted, and up to the times; and what does he do when *he* feels "bilious"? Take medicine? Yes, the very best kind. He gets out his horse and buggy and drives down to my place. Then he puts on an old suit of clothes, and, with dog and gun, takes a long rapid tramp through the woods and fields, until the sweat runs from every pore of his body. When tired out he comes back, puts on his dry clothes, and goes home all right. This has been his practice for years. How foolish, then, for *us* to dose ourselves with injurious medicines, which the most intelligent physicians, who know all that science has yet taught, on this point, wouldn't think of touching! And how much more foolish, and even wicked, to stuff the same down the throats of the little innocents, every time they cry or are fretful! There isn't a single drop of medicine in our house, of any kind, nor a single herb to make any of. We have always let nature take care of all little ailments, doing what we could to assist her by good care, and for larger ones called an intelligent physician, and I am sure our babies gave less trouble than mother's used to.

I know it is hard to sit idly by and see loved ones suffer, hence we try to prevent it by giving them pure air, sunshine, keeping them clean (of that in my next), feeding them properly, and seeing that they take plenty of exercise. Sickness usually comes as the result of violating the plain laws of health. It is Nature's protest against ill treatment, and Nature is the greatest physician on earth, and seldom loses a patient if given a fair chance. T. B. TERRY.

Hudson, Ohio.

HOW MUCH MONEY CAN I MAKE FROM THIS YEAR'S CROP?

THE PROFIT IN BEE-KEEPING AS COMPARED WITH OTHER OCCUPATIONS.

YOU ask me, on page 732, how much money I made after my tribulations. Really, I do not know, for I have not made it yet. I got, in round numbers, 3000 lbs. of comb honey and 1500 lbs. extracted, with enough to winter on. If I could have kept swarming within any bounds I should have had 1000 lbs. more. Of those 4500 lbs. I have about 4400 lbs. yet. I can scarcely sell a bit of it at any fair price. Last year I put my honey in stores in the villages around, at such a rate as to net me 15 cts. per lb., and it sold pretty well. This year I have put the price down about 2 cts. per lb., and there it is. Why? Simply because all who want it can get it from 8 to 11 cents. I have made efforts to sell some in Springfield, but have found the market completely stocked. I could have sold some at 10 cts., but —I would not—not yet awhile! I must have $400 out of my crop if I can get it, and not till I find I can not will I take any less. For the capital and work invested, that is not a high figure. As I do not expect to average over 8½ cts., if that, for my extracted, I must have more than 10 cts. for comb honey. Every farmer with a few bees had some surplus honey this year, and they have been running into market and lumping it off to get rid of it. They have it in pound sections too. In respect to the shape in which honey is put up, modern bee-keeping has made a wonderful stride in the last three years.

SOMETHING ABOUT OVERPRODUCTION.

I am convinced, however, that there is no use in trying to keep up the price of honey very much or very long. We must simply bend our energies to lessen the cost of production. It is folly to talk about quitting the business. If we do, what shall we go into? Shall we take up farming? For several years the wheat has turned out poorly in this region. This year there was a fair crop, but it is a fact that farmers are scarcely any better off, because of low prices. Last winter the live-stock markets were perpetually glutted, and prices disastrous. During the last two seasons we have had magnificent yields of dairy and poultry products, with consequent overstocked markets, and prices that at times scarcely gave back the cost of production. Shall we try mercantile business? One evening last summer a stove and tinware dealer told me, as an example of the business he was doing, that he had that day taken in 60 cts., while his expenses were $5.00 per day. He was in the business only because another man had failed, and he was on his bond for about $6000. He bought the stock to save himself.

A grocer in the same city, Springfield, of 20 years' standing, told me that the grocery business had ceased to be profitable, largely because there were too many in it. During that 20 years, Springfield has been more and more absorbing the business of the smaller towns around it. Yet there are too many groceries for that business. Always and everywhere we hear the same cry of overproduction or overstocking. I feel that I have quite a burden in the stock of honey on hand, with no demand for it; but I do not appear to be much worse off than most of the others.

There does appear to be

ONE PROFITABLE BUSINESS.

In my conversation with this same grocer I made observations similar to the above, when the gentleman admitted that no business seemed thriving except the saloons. There is a point for us all. This traffic in vicious indulgence lives and grows at the expense of the more legitimate and beneficial pursuits. How many pounds of honey, and how many bushels of wheat or potatoes, might be readily sold that are now glutting the markets, were it not for the millions wasted thus! And, by the way, that same stove-dealer, in our conversation, remarked that business lots on his side of the street were worth only half as much as those on the opposite side, because "the saloons along here" make them so undesirable for business purposes. Amazing fact! Who ever heard of any other profitable business but would enhance, not depress, the value of real estate in contact with it. Bee-keepers, in common with men in other occupations, can none too diligently inquire how best to get rid of this parasite that lives and feeds upon the very life of the business world. Friend Root, you may regard this as a digression, but I do not. I have, however, long been wishing for a chance to drive a wedge in here.

QUEER IMPRESSIONS.

I, too, get mistaken impressions concerning contributors to bee-journals. I was never more surprised than I was to learn that Mr. Heddon is a "little nervous fellow," instead of a burly, solid 250-pounder. A. I. Root, I have always taken to be a short, but thick-set, broad-shouldered, broad-chinned, short-necked man, a little inclined to corpulency as he grew older, with more of the sanguine than the nervous in his make-up. Am I right? GEO. F. ROBBINS.

Mechanicsburg, Ill., Sept. 24, 1886.

Many thanks, friend Robbins. In your remarks upon overstocking you touch indirectly upon the same point brought out by Dr. C. C. Miller—see page 811. You say, last year you sold your honey for 15 cents without much trouble. This year the farmers about you, perhaps incited by your success, have taken up the bee-business. Two results have followed: Your locality has become overstocked, and the price of honey reduced. If you were first in the field, is the honey in the locality over which *your* bees fly yours, or the property of every one else?—Our country is large, and there is an abundance of room for us all.—I believe it is a fact, that the returns from the honey-business average as well as those of other legitimate trades or professions, and I see no reason why we should become discouraged, even if our bees do not pay well some years.—It is true, there is *one* profitable business, and that it is damaging to every other legitimate business: but we hope this state of affairs won't exist many years longer, in our fair land.—Your impression of A. I. Root *is* queer, indeed. He is small, medium build, not thick-set nor broad-shouldered, and, least of all, inclined to corpulency. He is of a nervous make-up, impatient to have things move, and is never at rest during the hours of daylight. ERNEST.

I will add to what Ernest has said, that, as so many friends at the convention asked what I weighed, I have just ascertained. It is 130, and I believe I never weighed any more. For several years I have been averse to getting weighed, because it seems to me too many people waste valuable time in getting weighed every day or two. Now, all this is of but little moment compared with the point you touch upon, that all our industries are overdone. Intemperance is, without doubt, the *greatest* cause of this state of affairs.

NORTH - AMERICAN BEE - KEEPERS' SOCIETY AT INDIANAPOLIS.

IT was my good fortune (as you may guess from Ernest's talk, under the head of Our Own Apiary) to have Dr. Miller for a traveling companion. Indianapolis is a beautiful city. The streets are broad, and, compared with New York and Boston, it is a wonderful relief to see plenty of room for vehicles, pedestrians, and all the business that is to be done. Of course, there is no such amount of business done in Indianapolis as in the eastern cities mentioned; but I think they have done a very wise thing in laying out the city and distributing the buildings, even with the business they do have. Over and over again I was reminded of our old apiary and old home, contrasted with our new apiary and our new home here in Medina. When we commenced here I feared I was spreading every thing over too much ground; but the lapse of half a dozen years has shown the wisdom of having plenty of room, plenty of air, and plenty of sunshine. It seems to me that one of the greatest obstacles in the way of doing business accurately and rapidly, that we have to encounter, is getting things in a heap and disorder, sometimes wasting more time than it takes to do the work, because of having our business *all in a heap.*

The people of Indianapolis seemed to be very pleasant indeed. As soon as we got into the convention and paid our dues we were furnished with a plain neat little badge by Mrs. Robbins, who contributed very much to the success and pleasantness of the whole convention. Where we went through the city we were recognized by these badges as the "bee-men," and it was very pleasant for me to find myself already introduced, wherever I went.

I found that the convention did not open till 9 o'clock on the second day, therefore I had four good hours to "have fun" before the convention opened. My usual hour for rising is 5 o'clock; but at the Occidental Hotel they did not allow anybody to have breakfast until 6, so that blocked my way some. I want to say a word right here about our large hotels—they do not seem to be calculated for busy impatient men like myself. After we sat down to breakfast it was twenty minutes before the waiter brought our viands; and at dinner-time, after we had finished our dinner we had to wait fifteen or twenty minutes more for dessert. May be there is no remedy for this state of affairs; but I would have a remedy in some way or other, at all hazards. The above hotel is a beautiful one, and built exactly as I would have it, in the way of plenty of room and plenty of air. The bill of fare is excellent, especially in the way of fruits and vegetables. Very nice green peas were on the table in October. In the market we saw beautiful strawberries at 50 cents a quart. The vender said they came from the city of New York, but he did not know how nor where they were raised. If any one who reads this can enlighten me on the point, I shall be glad to hear from him. Does any one know what would be the result of cutting off the strawberry-buds in the spring? Would it not make them blossom later? You know that, by pasturing or cutting off alsike clover, we induce it to give a yield of honey after white clover is gone.

Well, after I got my breakfast I started for the market-gardens of Indianapolis. I was abundantly satisfied with my search, and gathered many new ideas. Perhaps I was fortunate enough to give a few ideas to the boys I found on the ground at that early hour. They plant their celery in a double row, the rows being six or eight inches apart, and the plants are set so as to "break joints," as we term it. By this means two rows are banked with the same labor required for one row. As the ground was very rich they secured a fine crop in this way. By the way, they get stable manure in Indianapolis for *hauling it away.* The boys said the owners of the manure sometimes paid them for going after it, when they wanted it removed. They were astonished when I told them that we pay from fifty cents to a dollar a load, according to quality, and can not get enough at that. It seems to me that farmers and gardeners ought not to grumble while this state of affairs exists in the West. Nothing is sold by the pound, or, at least, few things. They sell lettuce in February for $6.00 a bushel; but in October they get only 50 cts. a bushel. I saw a beautiful patch of "multiplier" onions that are to remain out all winter. They say they pull them for market in February. Sometimes they winter-kill badly; but as a rule, enough are left to make the crop a very profitable one. Manure being so cheap, they raise almost every thing in hot-beds, and these cover an immense area of ground. The frames that hold the sash are movable. After they are taken away, manure covers the whole plot of ground from one to two feet. It is now being carted over the ground, preparatory to getting fresh manure from the city for the hot-beds for the coming winter and spring.

I enjoyed my visit exceedingly, and came into the hall at ten minutes after nine, feeling that, with the exercise of the morning, I could easily stand it to sit still indoors from nine o'clock until noon. Doctor Miller, who has been for some time the president of the Chicago Convention, and who is, by the way, to be president of the N. A. Convention, to be held next year in Chicago, remarked to me, while we were traveling in the cars, that it seemed to him that the time of a convention ought to be occupied mainly in getting the opinions of those present—hearing from each one in the room as far as possible. He said that in Chicago they had for many years ruled out essays and addresses. These can be given through the pages of our bee-journals, while a single subject can not be considered by a hundred bee-keepers all at once, except at a convention. It seems to me there is much wisdom in this, although it is true, many times, that it seems to be desirable to discuss essays which have been read.

Discussion on wax-extractors, and the hints communicated by a great number of different people, were very valuable. For instance, friend Dadant said that where wax is extracted by steam, by no means let the jet of steam strike the wax. Run the steam-pipes down into the water contained in the tub or cask. When it gets the water boiling hot, throw in the pieces of comb. Direct steam has a tendency to get the wax into the well-known granular state, from which it is very difficult, many times, to restore it. Many reported having used the sun wax-extractor, and all declared themselves highly pleased with its use. It is practical, however, for only small quantities of wax. Steam is best for a large lot. Put only as much comb into the solar wax-extractor as will be melted quickly, and take away the wax often—each day if convenient. Cappings are rendered nicely with the sun extractor, and the honey that comes from them will be found under the cake of wax, good enough to put on the table. In fact, the honey adhering to the cappings is of the very best quality, although it is sometimes darkened by bits of pollen, etc., that get into it. Friend Dadant says they let their cappings drain a great deal longer than most people. Sometimes they put them on the sieve of the uncapping-can, and let them stand three or four weeks. When all the honey has run out that will run out, put on another lot, and so on. He says they sometimes have several barrels waiting to be thus drained out in the uncapping-can.

The subject of foul brood was discussed at considerable length. Members who had had experience with it gave reports that seemed to indicate to me that the course we have taken is about the best one, all things considered. At the present writing, the disease has not appeared in any case in any of the fifty colonies where the combs were destroyed; and nearly, if not all of them, have been raising brood right along ever since they lost their original set of combs.

The Chapman honey-plant was presented by two of the committee who were appointed a year ago to examine it and report, L. C. Root being absent. All who have tested the plant seem inclined to give it a front place with plants cultivated for honey alone.

Spreading brood to induce the queen to occupy more combs, and to put the brood in a more compact shape, was discussed at considerable length by many very able bee-keepers. I believe the general opinion is, that judicious spreading, in the hands of an expert, may greatly increase the amount of brood on hand at the time when honey begins to come in; but it is also true, that mixing up the combs, before the colony is strong enough to be able to bear it, may be a very great hindrance in getting a colony ready for the honey-harvest.

It is considered quite advisable to contract the colony, during winter and early spring, on to as few combs as will hold the stores and accommodate the queen; and this is best done by movable division-boards. Now, when the queen and bees both need room, *without any mistake*, move the division-boards so as to make room for one more empty worker-comb. Make this empty space pretty near the middle of the combs, and put in here your frame of empty comb. The worker-bees will almost at once prepare these empty cells for the reception of eggs. Very often the queen will have the comb partly filled with eggs before night. As these eggs are deposited all about one time, they require the attention of the nurse-bees almost at one time, and hatch almost at one time.

Whenever I attend one of these national conventions I am powerfully impressed with the advantage it is to any one to meet with the progressive and thinking minds of our age. To look into the faces of these men, and get intimately acquainted with them, is a powerful exhortation of itself. We sometimes get an idea that we are working alone in some of these unexplored fields; but to see some good brother get up and tell how he has gone away beyond us, oftentimes, shows us little conceits that we did not before suspect in our own hearts.

Of course, to get the full benefit of the purpose of the convention, we want every one to give some of his experience, or, at least, as many as possible; and when a single thought is held up so that one after another can give his experience in years past, it reminds me of concentrating the rays of the sun upon a single point by means of a powerful burning-glass.

A REPORT FROM AN A B C SCHOLAR

WHO FURNISHED US THAT NICE SECTION HONEY.

MR. ROOT:—In commencing to give in my report I will begin with the fall of 1884, when I went into winter quarters with 45 colonies packed in sawdust on their summer stands. I lost five colonies in wintering, on account of the severe winter. Over one-half came through weak. They increased from 40 to 67 by natural swarming. They gathered 1850 lbs. of white clover and linden honey, which I sold on an average of 15 cts. per lb. I packed my bees the same as the fall of 1884; lost two in wintering, which left me 65 to commence the season. I sold two swarms for $17.00, used three for queen-rearing. This left 60, which I ran for comb honey, giving me 2100 lbs.—an average of 35 lbs. to the colony. I kept 100 lbs. for home use; for the rest I received 14 cts. per lb. They increased by natural swarming to 98 colonies.

Basswood was an entire failure. The drought destroyed the white clover the first week in July. A field of alsike clover helped me in securing the quantity as well as the superior quality. After using 2000 of the 4¼×4¼×1⅞ sections with separators, and 4000 of the 4¼×4¼×1⅝ without separators in the last two seasons, I am so well pleased with the 1⅝ section I shall use them in the future.

By working hard I have made a home market for all my honey. The secret is, I think, to be found in putting it up in the most neat and attractive shape possible. This report is from an A B C scholar who commenced four years ago, with bees in box hives, which I transferred to the Langstroth hives.

M. G. CHASE, 15—65—98.

Lafayette, O., Oct. 5, 1886.

Our friend Mr. Chase has furnished us, for two or three seasons back, the nicest section honey it has been our lot to handle. In every instance, wherever his honey has come in competition with other honey, his has commanded a higher price. We sell his honey at 18 cts. per lb. on the market-wagon, while our other comb honey commands but 12 and 15 cts. Why is this difference? Because the Chase honey-comb is always pearly white, and the sections are never soiled with propolis or dirt. He packs his section honey in the 24-lb. single-tier shipping-case, and these in a light spring wagon which he takes wherever he can get the best price. Brother bee-keepers, are we all as careful to have our honey in as nice marketable shape as we can put it? In securing this honey he practices contraction, and uses the Heddon crate.

A GOOD REPORT FROM A BEGINNER.

ALSO A FEW KIND WORDS.

As the honey season is over, I feel as though I should like to say a few words in regard to the season, and other subjects of interest. I began last spring with six colonies, three Italian, one hybrid, and two black. Two of the Italians had about a pint of bees in each. I built them up, and they gave me one swarm late, but no honey. The other four I have increased to twelve, and taken 230 lbs. of honey—75 lbs. extracted, the rest in 1-lb. section boxes. The best Italian colony gave me three natural swarms and two artificial ones, and have given me 100 lbs. of honey. The season began early here, but there was hardly any honey in fruit-blossoms, raspberry, or dwarf maple—just the reverse of last year, when every thing was full of honey. The first of the season the bees got just enough to carry from one day to another, until clover, which also yielded sparingly, but lasted longer than usual, with just enough linden and buckwheat to keep them breeding well until goldenrod and asters opened about the first of August. These have given me all the honey I have taken, except 20 lbs. of clover in July, and from 20 to 30 lbs. in each hive to winter on, in nice heavy combs; they weigh from 5 to 8 lbs. each, capped, most of them clear to the bottom-bar. The honey is so thick that I could hardly throw it out with the extractor, and it weighs plump 12 lbs. to the gallon. It doesn't seem as though they would have much disease on such food. I don't think they have much pollen. I have sold 160 lbs., almost all at 25 cts. There is another bee keeper about three miles from me who has about 50 colonies. He sold his honey last year, what little he had, at 25 cts.; and when I began selling at 25 he did not like it so very well. He said I should keep the price up to 30 cts. for comb, for he was selling extracted at 25. There are few places where honey sells as high as here; but the town is small, and the people don't eat much honey, so it is rather hard work to sell at that price. I know that it is a good price for honey. I suppose 20 cts. is about right for it here; but if I should drop to 20 cts. this friend of mine would be very much offended, and give me another lecture on underselling. He said he could sell all the honey he could raise, at that price, and mine too, but I don't think he could. Some will buy honey at any price, and there are a lot more who will not unless they can get it cheaper. I took about 40 lbs. to Plymouth, quite a large town twelve miles away. I sold it after a while, a little in a place, but the most of them said they could send off and get it and then sell it for less than I offered it to them. I have pint 1¼-lb. jars at 45 cts.; how do you suppose it would work for me to fill all the stores with them at 30 or 35 cts.? Could I make more in the long run by so doing? I want to sell a lot of honey, but I want to do right, and use everybody well. Of course, it would not do to sell for less in one town than another. I should like a little of your advice on this subject, if you would be so kind as to give it.

How the bees did work for four or five weeks! If they had done as well the first of the season, I might have had quite a little report; but five good swarms and 100 lbs. of honey from a colony is not very bad. I am well satisfied with my work this season, and I owe most of my success to what I have learned from GLEANINGS. How any one can find fault with the contents of GLEANINGS is more than I can conceive. Every word of it is interesting to me, and instructive. Your talks about gardening, carp, poultry, and every thing else, is, to my mind, good enough. I wish it came every week.

I am sorry you have foul brood, and hope you will soon get rid of it. The smoker you sent me last year, for quitting the use of tobacco, has done me good service this season. I have not tasted the weed since, and don't intend to again. I am very much obliged to you. I have thought, this summer, if the men of this town would use the money to buy honey with that they pay for tobacco, I could sell honey enough; but they think tobacco is more of a necessity.

C. E. WATTS.

Rumney, N. H., Sept. 29, 1886.

As a general rule we should get as good a price as our honey will bring, and I hardly think 25 cts. per pound is too much if our patrons are willing to pay that for every pound we can raise. On the contrary, if customers will *not* buy at this figure, then we must sell for less. Your neighbor and yourself, I think, can come to some amicable agreement as to the price per pound you can dispose of your whole crop of honey. In regard to the 1½-lb. jars, if they will sell so as to in time close out the whole lot at 45 cts., I do not think I should drop the price. Questions of this nature, each one must decide for himself to a greater or less extent; and while we should command as high a price as we can get, we should also remember the "Golden Rule."

CATNIP.

Its Value for Medicine as well as for Bees.

ALSO SOME GENERAL THOUGHTS IN REGARD TO THE MEDICAL PROPERTIES OF PLANTS.

THIS very common plant grows all over our country, yet very little is known about its real value, because it grows at almost every man's doorstep. Something far fetched and dear bought is considered to be very valuable, while we have as good, and perhaps better, all about us; and if the one at home were carefully studied, our introduction would lead us to say, "We wish a better acquaintance." The medical properties of this plant are anodyne, carminative, diaphoretic, anti-spasmodic, and nervine. The infusion given cold is a mild tonic; so also is the fluid extract. It has been used in febrile diseases as a diaphoretic, and to promote the action of other remedies; also to allay spasmodic action, and produce sleep; and right here its value has been tested thousands of times, when the fever has run high, and the poor sufferer has rolled from side to side, wild from feverish mania, the eyes glaring and bloodshot, pulse 130 per minute, temperature 104, respiration 30. Now, here is a case that any physician would regard with alarm, and well he might, for danger is near if this condition is allowed to remain, or can not be removed. With the danger-signals all up, give *four ounces* of a fresh infusion of *catnip*, warm as can be drank comfortably, every hour, for 6, 8, or 10 hours, and, lo! your signals are all down, or, at least, at half-mast. Every indication is *changed for good*. It has been given as a carminative and anti-spasmodic in the flatulent colic of little children. Many times I have seen the little sufferer soothed down to rest and a long sweet sleep, by the use of a few teaspoonfuls of catnip tea; a gentle moisture would spread over the whole system; the irritation or cold, as the case might be, would fly out of the windows (the relaxed pores), and the little one would be well.

It is of great value as a *uterine* tonic, and has proved very beneficial in amenorrhea and dysmenorrhea, and has been employed in nervous headache, hysteria, and nervous irritability. The proof can be furnished, if the proof of the action of any medicine can be furnished, that it has restored the menstrual secretion after other means have failed.

As a convenient domestic remedy it has no superior in recent colds, coughs, febrile and eruptive forms of diseases, which infants and young children are subject to. The leaves and flowers are the most valuable part of the plant, and the virtues thereof are set free by boiling water, except the essential oil, which can be procured only by distillation. It contains that variety of tannic acid which strikes a green color with the ferruginous salts that are set free by heat. Restlessness, arising from overwork, anxiety of mind, and many other nervous conditions, are soon improved by the use of this remedy. The fluid extract of catnip, ladies'-slipper, and skullcap, equal parts, forms a splendid remedy for chronic nervous headache.

But with all the other good qualities, it is a splendid honey-plant, supplying a large secretion of nectar for the busy bees every year, and sometimes the amount of honey gathered from it is astonishing. And while it is good for the bipeds and good for the bees it is also good for Tabby. A few years ago I had a very fine puss that began to be stupid, and dumped about for several days, refusing all food, even milk. One day she had a terrible fit, frothed at the mouth, jerked, and convulsed terribly for a few minutes, and then a faint moan escaped the poor creature, and my sympathy was stirred beyond further endurance. I got some catnip, made some tea, and gave it immediately; and as soon as it touched her mouth, the greatest pleasure was manifest, working her mouth and trying to get every drop. In a few moments she revived, and lay quiet and resting. After a little while she moaned again and I gave some more tea, when she took greedily all I gave her. She took several drinks of it during the day, with the greatest possible relish; and the day after, she began to take a little food, and recovered rapidly, without having any more convulsions. If my horse had been sick, and recovered as nicely and speedily as did my pet Tabby, I should have regarded the remedy used, whatever it was, as very wisely applied.

The physician who does not deal truthfully with suffering humanity, especially when he knows that death is but a step before them, is very unkind and cruel. Ignorance or dishonesty only can be attributed to such conduct. If ignorant, he is unfit for a professional position; if dishonest, he is just as unfit.

N. L. HIGBIE, M. D.

Elsie, Mich.

I presume, doctor, the above was called forth by my questioning whether catnip really possesses the medical value that it usually has credit for. No doubt you are right, and I thank you for the information you have given us in the matter; but please, doctor, excuse me, and I would also ask the rest of the brethren who belong to the medical profession to bear with me a little, if I ask for a little more light on the subject. Suppose I should drink a gallon of the strongest catnip tea that could be made, inside of 24 hours, would it do me any harm? I presume that all would agree that it would not. Now, is it not possible that the warm drink, many times, does the work, when the catnip has the credit? A good big dose of hot water, just as hot as you can possibly swallow it, will, many times, do wonders. When I am out in the rain, and get chilled, and I can feel the premonitions of a tremendous cold coming on, I have often rushed for the kitchen stove. If nothing else is handy, I get a good dipperful of hot water from the reservoir, then I get my feet in the oven, and drink and drink. Now, it may be that an infusion of catnip in this hot water would help it, but I can't feel quite sure of it, unless the matter has been carefully tested by earnest searchers after the truth. I did not think of questioning the truthfulness of our medical men, nor have I been so uncharitable as to suppose that any reliable physician would fail to do his honest duty whenever his services were called for, unless, indeed, it were one of the kind of doctors who sometimes get intoxicated; and if I were taken sick when none but the latter kind could be obtained, I think I should feel safer with the dipperful of hot water.—In regard to catnip as a honey-plant, we raised it on our grounds quite extensively; but the cultivated plants, for some reason or other, died and went to seed so soon after they had given a good crop of honey that I decided they were too short-lived to be allowed to occupy very much space where land is as expensive as our own.

WHERE IS OUR GOAL?

THE COMING BEE.

FOR the last few days I have been thinking over and over again of a wonderful sermon that I heard from the pulpit a short time ago. The preacher—a very earnest man—tried to impress as forcibly as possible this thought upon his audience: That all people, in order to grow, to unfold, to ripen into perfect characters, must have a model—one that they must reach up to, and that a perfect one—even Christ Jesus. Ah, how true this is! Just show me the man or woman who is content to let things slip along in the same old rut, year after year, and I will show you a person whose growth can not be seen. Why? Because such persons have no model. These people have no ambition—no goal. If they had a goal which they were aiming to reach, then, when they compared their progress side by side with this sample, they could see their gain, or loss and profit thereby.

I do not wonder that you or Ernest exclaimed, in Our Homes of Aug. 15, relative to the indolent shop-keepers, "Why can't they jump up and push something?" But, again, the pastor said we should be acquainted, or familiar, with our model or sample, that we might compare or measure ourselves and our work by it, and thus see when we have attained perfection, or how near we have come to it. It was this phrase that led me to see how well the sermon could be applied to our vocation—bee culture—as well as to our lives, and in this manner:

Have *we* a goal? If so, what is it? We talk and write of the coming bee—what is it? Who can describe it? If we do not know exactly what we want in our ideal bee, or if we are not familiar, either through writings or our thoughts and ideas respecting it, then how can we tell when we have procured a perfect bee? and would any two bee-keepers agree as to its worth?

Map out the bee we all want; discuss each peculiarity, each merit that it must possess, then let us compare each race or strain by this model and see just what is now lacking. Let bee-keepers work *together* for this end. "United we stand, divided we fall." Combine traits that we think will improve our existing races, and how long would it be before we should see a wonderful improvement?

And how is it with hives and fixtures? See the variety of hives, etc., in use to-day; their names are legion, and the evil seems to grow instead of diminishing. Is this the way in which we are to gain rapidly in apicultural science? No. As with bees, we must find what we need; what ends are to be accomplished, then all work for them. Have our energies concentrated; our ideas culled, and then just imagine the progression we should make, and see if all this could come to pass.

To be sure, we are progressing rapidly, even now; but each of us seems to be struggling on for some *unknown* or indefinite end. If I should ask such men as Messrs. Doolittle, Cook, Root, Hutchinson, Heddon, and a host of other leading men of the science, to just what height apiculture is tending, what means are being used to get there; and if they are familiar with the goal we are striving to reach, so that they could tell when it was gained, or compare our yearly progress by this perfect sample, what would be their answer? I certainly could not begin to answer the questions, but probably they could.

I have always been eager to adopt new ideas or inventions, and have prided myself on my progression; yet I realize that I am at a loss to know just what I really want. Of course, I can see, as can all bee-keepers, wherein gain could have been made in certain points; but one or two, or even a *score* of men and women, are not to accomplish, though they may work hard, what will require the combined efforts of the whole bee-keeping fraternity.

It has always seemed to me, that if Heddon, Langstroth, Quinby, and Root, or all of our prominent inventors, could have come together and *worked* together on things needed, that more could have been accomplished than is now on record; although, mark you, I would not in the least underrate the immense knowledge they have already given us. C. H. SMITH.

Pittsfield, Mass.

Friend S., I agree with you in regard to having a goal and a model; and I think, also, that it would be a very excellent idea to map out, as far as we can, just what we do want. I should like bees that gather honey when ordinary stocks such as we now have get nothing. But perhaps when we get this we may find that we have got, along with it, a great propensity to rob; so the matter is going to be somewhat complicated before we get through. The thought expressed in your last paragraph is what we propose to accomplish by bee-keepers' conventions.

LETTER FROM INDIAN TERRITORY.

A SWARM OF BEES FOUND FIVE MILES FROM ANY TIMBER, ON THE OPEN PRAIRIE.

WHILE driving in an adjoining country, some 22 miles from home, I captured a runaway swarm on a large prairie, five miles from the nearest timber in the direction from which it came. I chased them nearly a mile, and succeeded in getting them into a flour-sack, and brought them home the same day and hived them in a new hive, as described by Dr. Tinker, and illustrated in GLEANINGS for Mar. 15. They have done well, and are now storing honey rapidly from Spanish needle.

A FAVORABLE REPORT FROM HIVES USED HEDDON FASHION.

In regard to the hive recommended by Dr. Tinker, I will say that I made half a dozen, and hived prime swarms in them, using two sectional parts for brooding and alternating, placing sections in the case on top of same, with no kind of honey-board between. In each case, where I used the 4¼ x 4¼ sections they were nicely filled and sealed. Upon one where I used sections 4¼ x 8½, the queen went above. For comb honey I very much like said hive; but from the description, I am of the opinion that the new Heddon hive is superior.

LONGEVITY OF IMPORTED QUEENS.

My imported queen, purchased of you late in the season of 1883, died the following winter, without leaving me a single one of her daughters. I wonder how many of your A B C class have done the same or nearly the same thing. Of course, if I had succeeded in getting a large number of extra good queens, noted for usefulness, you would have had my report sooner. I resolved to tell you this, even if it is seemingly adverse; but such adversity only makes me the more careful, and appreciate success more when it does come.

MY REPORT.

From 8 colonies I have 400 lbs. of extracted honey, 100 lbs. comb. My best colony has given me 10 gallons, and I shall probably get 1½ gallons more. The queen was purchased of G. A. Beech, Quitman, Mo., and is extra prolific.

4—W. H. LAWS, 12–25.

Pocola, Ind. Ter., Sept. 22, 1886.

Thanks, friend L., for the valuable fact you give in regard to the distance a swarm of bees may travel. — I am glad to hear that you succeeded so well with the hive made as mentioned.—Where we sell imported queens late in the fall, we presume they will, of course, live long enough to be of some use next season. Queens, however, like other farm stock, are liable to die at any time, and without any apparent reason. In consideration, however, that you secured no young queens from her at all, we will furnish you another at half price, any time when you feel inclined to order. I believe that imported queens have not, as a rule, proved to be shorter-lived than other queens; and in some cases they have done good service for two and even three seasons.

FOUL BROOD.

FRIEND DOOLITTLE TALKS TO US ABOUT IT.

IT seems to be a way we bee-keepers have, of discussing a subject "to death" when once we begin on it, and for this reason I had thought I would not say a word regarding foul brood; but as some errors have crept into this foul-brood discussion, as I view them, I can not well hold my peace, for I deem it wrong to allow an error to pass unnoticed. First, I wish to call to notice that the phenol cure was brought forward to cure *Bacillus alvei*, which, in my opinion, is not our foul brood at all, if we take Mr. Cheshire's description of it, found on pages 644 and 740 of *A. B. J.* for a truthful outline of said disease. He then says the disease is not carried in the honey, while our honored M. Quinby said that it is, and hundreds of bee-keepers can testify to the truth of Quinby's words. He further says, "There is not a single old idea about this disease (foul brood) which is not incorrect, except that it is contagious." Again, he tells us it is a disease of the mature bees, and that even the eggs of the queen contain *bacilli*, he having counted "no less than nine" in an egg. All this proves to my mind that *Bacillus alvei* is not our foul brood, even although Mr. Cheshire says it is, and that phenol is a remedy for only the first, and not the last. I always prize scientific researches highly; yet, to be valuable to me such research must not run squarely against facts known to exist from practical experience. Hence I think there is an error somewhere, so I am, like friend Root, skeptical regarding the phenol cure.

Again, Mr. Hoyle is putting forth the idea that the disease is caused by inferior honey, and that it can be cured by feeding "nice honey from flowers or sugar syrup," all of which convinces me that he never had the genuine foul brood as it existed from 1855 to 1875 here in New York.

Malignant foul brood is always aggressive, never retrograding; and although there are times during a heavy honey-flow when the bees make a desperate effort to clean it all out, yet, as soon as that flow ceases, even an inexperienced eye can tell that the disease is surely and steadily advancing, so that in less than one year from the time many cells of foul brood are seen, the colony must succumb to the inevitable; for by that time the combs have become literally a putrid mass. All other diseases of the brood will get well, as Mr. Hoyle speaks of, and would succumb to the mild treatment of coffee, as Mr. Vance tells us about; but the genuine is not gotten rid of so easily. I have not seen a genuine case of foul brood in ten years, and I very much doubt if friend Root has had real foul brood in his apiary. At any rate, I think he has been a little hasty in destroying those affected colonies by fire; for if it were not foul brood, bees by the colony make rather expensive fuel. Just what I should do in a like case would be, when I found a colony which gave appearance of foul brood, I would carefully note the number of diseased cells it contained, and the strength of colony, after which I would close the hive and let it alone for two months, when, just at night, when there was no danger of robbing, I would again examine it and compare notes. If not materially worse, I would again wait another two months, knowing, of course, that there was no danger of its getting so weak that it would be robbed out. If at the end of four months it should be no worse, or had got better, I would call it all right; for by this time the genuine foul brood would have so spread that at least half the brood would be dead, especially in the summer months. If it proved aggressive, I would take the course friend Root has, providing only a few had the disease. If many had it I would treat them on the Jones plan, only I would not starve them as he does; for from my experience with it in 1872 and '73 I can see no need of this starving process; for if swarms from a foul-broody colony, placed in an empty hive, do not have any of the disease, driven colonies will not. Colonies so hived in 1872 did not again have the disease, while driven colonies were left in an empty hive till larvæ began to hatch, when combs and frames of brood were given them, and no signs of the disease appeared afterward. By this plan I secured six frames, partly filled with nice worker-combs, which were afterward completed with nuclei, which I should have lost had I used the plan as Mr. Jones uses it. If not wanted as above, these combs are splendid to use in sections, *a la* Walter House, so in this way those six days of fasting are made to be of value to the unlucky apiarist. Having once "been through the mill" with the genuine, I know whereof I speak.

Borodino, N. Y. G. M. DOOLITTLE.

Since our last report I (Ernest) have been through the apiary personally; and now, having examined half the colonies, I have found five of the very *worst* forms of foul brood I have yet seen. I was scarcely able to find a healthy cell, in said cases, but, on the contrary, the brood was fairly rotten with the disease. The cells were sunken, and in many cases the characteristic small hole in the cappings was seen. The young diseased larvæ have that brown, maturated, sticky appearance. If a toothpick be dipped into such a cell, the matter will adhere to the point when withdrawn, forming a fine thread. The older larvæ shrivel into a brown color. The disease certainly has a hold of us, is contagious, and is spreading. So far, we have had fifty cases of foul brood. I have found all stages of it in the apiary, from one hive with only an occasional diseased cell, to one having the combs fairly rotten. No, friend Doolittle, were you here to take a look into our colonies, you would be no longer in doubt. We should like "awful well" if we could *believe* that we didn't have foul brood, and I do think I should throw up my hat and yell if such were the case. Now, perhaps you will ask, "How is it that we reported no foul brood in the last issue, and have it so badly now?" For some reason our apiarist has not caught on to the knack of finding it; and as he stated that he had found no foul brood, it was so reported in GLEANINGS. Feeling a little doubtful that such *could* be the case, I went at it myself and arrived at the results as above recorded. See reply to the following article. ERNEST.

FOUL BROOD.

ITS NATURE ILLUSTRATED BY EXPERIMENTS.

IN writing this article I believe I am prompted by nothing but a real sympathy for you in your misfortune—foul brood in your apiary. On page 734, in one of your foot-notes you make this unqualified assertion: "In spite of all we *can do*, it continues to exist in our apiary." Now, it does seem to me that, if this assertion is to be taken with all the force that the auxiliary verb "can" gives it, that it would be inconsistent to contend any longer with the disease; but as I think it continues to exist in spite of all you *have done*, rather than in spite of all you *can do*, I shall offer you a bit of experience in connection with some experiments with foul brood in my apiary. But let me first remark, that, as foul brood is caused by a microscopic vegetable growth, I would proceed upon exactly the same principle to get rid of it that I would to get rid of Canada thistles or any other vegetable growth; namely, destroy every living plant and every existing germ. Then, and not till then, have you conquered. But, to proceed:

A few years since, I had in my apiary one colony affected with foul brood. Just what I did was this: I exchanged the cover for a new one. I caged about a pound of the affected bees, took one comb containing honey and pollen, without brood or bees. I then smoked the colony at short intervals for several hours, until every bee was in. I then smoked them with sulphur until every bee was dead. I then carried the hive some rods from the apiary, where I dug a pit, in the bottom of which I burned the hive with all its contents. The affected cover of comb card and caged bees I placed beyond the possible reach of bees. I then formed nucleus colonies, and waited twenty days, that I might have plenty of brood in my nuclei.

Now I will here remark, that up to this time no trace of the disease was discoverable in the apiary. Now for the experiment: In nucleus number one I dropped down, between two of the frames, a small section of the affected cover, and burned the remainder of it. In number two, upon the top of the frames I placed a small piece of enameled cloth, upon which I emptied my cage of bees, which by this time were not only dead, but so decomposed that they had ceased to throw off any unpleasant odor. In number three I placed a small quantity of the affected comb, from which I had carefully washed all the honey. To number four I fed a quantity of sugar syrup, made with the water that I had used in cleansing the above-mentioned piece of comb. In number five I placed a sheet of foundation suspended in the aforesaid affected frame. After carefully scalding, I scraped it in such a manner as, if it were possible, to destroy every germ of foul brood. The result was, in a short while every colony thus experimentally treated had foul brood. This drove me to the conclusion that the only true remedy is to burn the affected hive with all its contents, and every thing else, indeed, however valuable, with which any foul brood had come in contact.

Just here I will remark, that I plowed the apiary ground; burned the saw, hatchet, smoker, and other things that had been used in the above experiments, together with the five affected colonies in the bottom of the above-mentioned pit. I then filled the pit with dirt, burying the ashes some two feet beneath the surface. I had one case after this, to which I gave the double rite of cremation and burial, and thus ended my experience with foul brood.

Now, Mr. Editor, it seems to me to be the plainest of propositions, that if foul brood depends upon a vegetable product for its origin—and I suppose that no well-read bee-man would deny this proposition—that the method indicated in the above experiments is the only one left us with which to conquer this terrible disease.

As I am conducting a poultry-yard in connection with my apiary, I will give you an item from it. Last July I set eleven hens on 143 eggs. They did not hatch very well, as only 101 chicks were brought off. I caged ten of the hens and gave the 101 chicks to one hen. Our three-year-old boy stepped on and killed one; two I killed, burned, and buried, because they showed symptoms of gapes; the other died from an unknown cause. The remaining 97, at this writing, I see all in perfect health upon the lawn; and I assure you, to me this is one of the most pleasurable sights I ever beheld. Now, as this, at least in this section of the country, is unusual success, and depends upon a great deal of detail in the matter of handling, feeding, pasturing, and cooping, I will refrain from giving it unless it should be wanted.

The honey season continues to be a very poor one. Words would certainly fail me were I to attempt to tell you of our appreciation of GLEANINGS. "Sweet" and I have been seriously thinking of sending for an additional GLEANINGS, so that neither will be compelled to read stale news.

Hearn, Ark., Sept. 29, 1886. P. H. MARBURY, JR.

I grant, friend M., that complete extermination of hives, bees, frames—in fact, every thing connected with them, is a sure cure; but if a milder treatment will accomplish just as good results, why not use it? We have yet to find a single colony of the fifty, treated in the manner we have before described, that was not cured. We destroy the brood-combs and honey only. We put the bees into a clean hive on frames of fdn., and close them up for 24 hours, after which time we feed them. The hives and appurtenances are thoroughly scalded out with steam. I think it is true, that live bees will not give the disease, where, if they had been sulphured to death with the diseased honey still in their sacks, they would spread it, for this reason: The live bees will consume the honey in their sacks, containing the germs of foul brood, when the same honey in the sacks of dead bees will remain unchanged and consequently be contagious.

Once more: Your nuclei were together by themselves, and, in consequence, the bees of said nuclei probably did and must have intermingled to a greater or less extent. Then if one of the nuclei had foul brood, all would have it. It is this very same thing which we think is spreading foul brood at the Home of the Honey-Bees; so your experiments, although carefully conducted, it seems to me do not prove any thing. As a moral, then, I think it behooves us to have our colonies located pretty well apart.

ERNEST.

LEGISLATION NECESSARY.

DR. C. C. MILLER GIVES US SOME THOUGHTS ON OVERSTOCKING.

IN my last article I tried to show that the interests of all would be best subserved by having bee-keeping mainly in the hands of those who make of it a principal if not an exclusive business, and took the ground that legislation is needed to encourage the movement in that direction. At first thought, the necessity for this may not appear. Some may think the matter will regulate itself, and that, as a matter of honor, no one will encroach upon ground already occupied. Unfortunately, cases enough have already occurred to disprove this. I recall the case of G. M. Doolittle, reported by him incidentally as bearing upon some other point, with no thought, apparently, of finding fault with the existing state of things. I do not remember exactly, but I think that, by means of others in his field going into the business, his average yield was reduced about one-half. Mr. Doolittle's plan of dealing with these men who lessen his profits is to give them advice and assistance. Under the circumstances this may be the best way, for they have just as good *legal* right on the ground as he; but unless Mr. Doolittle is made of different material from myself, he would be glad to have them out of the way, and would be willing to pay a fair price for their permanent withdrawal. Suppose the same state of things existed in farming, so that a man with fifty head of cattle finds the ground for their grazing beyond control, and subject to the whim of every interloper. How long would he continue the business? Just so long as the present uncertainty exists it will be a serious hindrance. Even supposing that no investment whatever were needed in the business, the fact remains that any year a man may be compelled to seek a new field, possibly at a great distance, and at some expense in the search, and the expense of removal is a serious matter, to say nothing of the breaking-up of old ties. But as the business becomes more settled in its character there will be few without more or less of permanent investment that would be a dead loss upon removal. Buildings are put up, specially adapted to the business. Winter repositories are built in some localities, which are of little or no value for any other purpose. The matter of artificial pasturage would receive a strong impetus if a bee-keeper could feel sure of himself reaping the harvest of his own sowing. I am not over-sanguine as to artificial pasturage; still it is among the possibilities, that, not so very far in the future, there may be bee-farms of 10, 50, or even 100 acres, principally or wholly devoted to honey plants, making a continuous harvest from May to November. But what encouragement have I to invest in such an enterprise, with the probability that, as soon as fairly under way, the proceeds must be divided with others who have borne no part in the expense?

What kind of legislation is needed? I don't know. I have studied very little upon this part of the problem; but whenever bee-keepers are agreed that legislation is needed, some one will suggest a good plan. One way would be to dispose of territory in the same way that the soil was disposed of by government, giving one a deed of so many square miles, or of a township. But it is premature to discuss the kind of legislation needed, unless bee-keepers first agree that any legislation is needed.

A WHEELBARROW.

After greatly delighting my wife with a carpet-sweeper, and nearly as much with a lawn-mower from A. I. Root, I meditated sending to him for a wheelbarrow, as my old one was pretty well used up. It occurred to me, however, that I could so modify a common railroad wheelbarrow, for which I had but very little use, as to answer the purpose. It was very strong, but an awkward, heavy affair. I knocked off the boards that formed the body, or box, and sawed off the upper part of the standards nearest the handles, leaving a light and very strong barrow. Taking off the boards took away the stiffness, so I had two iron rods put on as braces. The load coming close to the wheel makes it much easier handled; and although costing only two or three dollars, I would not exchange it for any $5.00 wheelbarrow I ever saw. Railroad wheelbarrows may be found at almost any hardware store; and although made in different ways, I think any of them can be easily modified to suit a bee-keeper.

Marengo, Ill., Sept., 1886. C. C. MILLER.

Friend M., I have many times thought of what you say; and, in fact, when planting our basswood orchard it occurred to me quite often, that, should it ever prove a success, somebody would be almost certain to begin bee-keeping in the vicinity, and thus take advantage of our crop of honey which took us fifteen or twenty years to raise. In fact, a good many asked me what I should do if such a thing should happen. I told them this: That I should expect to keep enough bees to overstock the locality. In fact, I proposed to keep such a number of stocks at all times that it would be a very poor investment for a bee-keeper to locate very near me, and some have already found it so by trying. Another thing: Is not the competition in any kind of business something in the same line? When one gets a big trade started in the clothing business, for instance, somebody else takes a big part of it by running opposition. If the second man who comes in is a keen, go-ahead business man, clothier No. 1 frequently buys him out, with a written agreement not to go into business again for a term of years. Why should not a bee-man do the same thing? In defense of your position, however, I have very often thought I should like to purchase the privilege of keeping all the bees within, say, a radius of three miles in every direction. I should then have control of foul brood in a way that I have not got it just now.—Thanks for your suggestions in regard to remodeling the common cheap wheelbarrow. I am inclined to think, however, that when you come to see our $4.00 wheelbarrow you will relent a little—see if you don't, friend M.

THE LOW PRICE OF HONEY.

WHAT ARE WE TO DO TO STIMULATE THE TRADE?

I NOTICE in the bee-journals that honey quotations all say they have more than they can sell, and tell us not to ship just now, as it is slow sale. So it continues all the year, and from year to year. It won't bear shipping, the sales are too slow and too low. I shipped four barrels of extracted honey to Galveston a year ago. The merchant to whom I shipped it says that he has not sold an ounce of it yet. I see by the reports that the honey crop is large in the North this season, more people going into the business every year, doubling yearly or more. The fact is, people don't eat honey. They are very fond of it if it is *given* to them; but if they have to buy it, it gives them the toothache—makes them sick; in short, they don't like it. Well, we are in the business very extensively, and the question is, how to get out of it or get our money back. I have 400 colonies of bees in the Langstroth hive, and have extracted 600 gallons—a very light crop. I have to keep from three to four men nearly all the time to help me. I pay them 75 cents per day, they boarding themselves. That is very low pay for work among bees, yet I can't sell honey enough to pay the hands, not counting *my* time as any thing. There is no "let up" in the business. Bees don't care for Sunday. I can handle any bee that I ever saw, with a smoker, without gloves or veil, with my sleeves rolled up, yet it doesn't *pay*. The more honey I have, the less it pays. If I could get along without barrels to put it in, it would pay a little better. We shall have to put it in some other shape to sell. Can't it be made into candy? Can it be made so as not to run together like stick candy?

I have thought, that if we could get the newspapers to talk honey it would do much in aiding us in selling honey; there is not one man in ten thousand who ever reads a bee-journal, yet all read the common papers. I notice some bee-brother says that no bad reports of bees and honey are ever published. This will satisfy him that I am badly in the ditch, and I suppose that I am not alone, by many hundreds. You will have to put me low down in Blasted Hopes if some brother can't help me out in disposing of my honey. We all want help.

J. W. PARK.

Columbia, Brazoria Co., Texas, Aug. 17, 1886.

Friend P., I am inclined to think your honey is not first quality; that is, it probably does not command first price in the market. When we get a real nice article of either clover or linden honey, we seldom have it remain very long on our hands; but a lot that is a little off in color, or off in taste, goes off at a very low price. I am afraid, also, the merchant to whom you shipped it does not make much of an effort to sell it in the way of getting it before the people in attractive shapes. I do not believe much can be done in the way of making honey into confectionery. The honey-jumbles I have mentioned on former pages seem to be the best outlet for honey to be used in the way of refreshment. We are just finishing the ten-barrel lot we mentioned a few months ago, and the whole ten barrels have been sold in our own town. They will keep months, or even years, and are just as nice a cake when a year old as when first made. People don't seem to tire of them. The flavor of honey is very perceptible in these jumbles; but even a poor quality of honey seems to go off well when worked up this way; that is, I mean such honey as goldenrod, Spanish needle, or even buckwheat, when it is in the form of a cake, is not objectionable. Friend P., if you will send a sample of your honey to friend Muth, of Cincinnati, I think he can take it off your hands at a pretty fair price; that is, if the quality is fair. Your suggestion is a good one, about getting the newspapers to talk about honey. They are getting to, to some extent, but not very much as yet. Now, then, brethren and neighbors, can't some of us help friend Park out of his dilemma? It seems to be too bad to hear him say, that the more honey he gets, the less the business pays. That is certainly a queer turn of affairs in the bee-business.

BOTTOMLESS HIVES.

HOW THEY ARE USED BY M. BROERS.

AS I wrote you some time ago that I was experimenting on a hive without a bottom, and promised you I would report later, I will now give you the result of my experiments, and the advantages to be derived from the use of a hive without a bottom. In the first place (and I consider it of the greatest importance), there is no possibility of losing the queen when hiving a swarm by her getting under the bottom-board; and in the next place, I can put in a swarm in about half the time it takes to put them in a hive any other way, as the hive can be left open all around, so they can get in from all sides. I have not put in a single swarm from the top of the hive this season, and have not had one swarm to leave me, which, I think, is often caused by being compelled to go into the hive after the swarm is all in, to straighten things up.

Another advantage is, that you can give a new swarm all the air they need, and you know they need a great deal. Where the yard is located on a slope, as it should be, every shower we have washes out the bottom of the hive, carrying off all filth which may have accumulated underneath, and which, at the same time, makes it *very* unhealthy for the larvæ of the bee-moth, which, by the way, can find no lodging-place inside the hive.

Another item is the saving of lumber; and I think, taking all things into consideration, I shall never use another hive in my yard, with a bottom-board.

HONEY AS A CURE FOR ERYSIPELAS.

A neighbor lady tells me that she completely cured a case of this disease with honey, after the doctors had given her child up and said it could not possibly get well. The way she applied the honey was by saturating a sheet with honey and wrapping the patient in it; but it was a very bad case, and the disease had spread all over the child's body. I suppose all that would be necessary would be to cover with a cloth the parts affected, saturating it with honey. The above may prove of value to some of your readers, as erysipelas is sometimes very hard to control. M. BROERS.

Gonzales, Tex., Sept. 20, 1886.

Friend B., this subject is not new, and a good many have used hives without bottoms to a considerable extent, myself among the number; but when your bees unexpectedly get on to a robbing raid you may wish pretty vehemently you had got tight bottoms to all of your hives, and entrances that could be closed safe and tight. Perhaps in your warm climate there is not as much need of bottom-boards in general as there is here.

SOME EXPERIENCE WITH THE BLACK BEE.

FROM AN A B C SCHOLAR.

You say in GLEANINGS you are not bothered much with moths or worms. Well, I have had a great deal of trouble, and can hardly keep them from destroying my strongest colonies. I have one especially that has been losing the young bees for about two months past. I went a month ago to see friends Nebel & Son, of High Hill, Mo. I asked them why I was losing so many young bees, and they could not account for it. I guess from the questions I asked them about bees they thought I was too good an A B C scholar to let moth get in my hives; so after coming back home, and still continuing to study the A B C book, I at last found out by it that it was moths. Well, I went to that hive yesterday and just tore the combs apart. I found some moths, to be sure. I tore out combs with moth-worms in them to the amount of a gallon. I am having trouble this morning with robbers. I have four out of the six now that I can go through and take the moth-worms out.

The season started in well for honey, but it was very dry the latter part of summer, so that now my bees are not making any more honey than they are consuming, so I have to feed three of them for winter. Since starting in with bees I have become enthusiastic in bee culture; and to say I like the A B C book and GLEANINGS is putting it very mildly indeed. There are some writers I have learned to especially like already, such as the writers of Our Own Apiary and Banner Apiary, and Doolittle and others. I expect to build hives this winter, and think I shall adopt the chaff hive for lower story, and Simplicity above. There are a great many people here who have bees, but they get very little honey from them, because they keep them the old way; but I think a great many of them will soon adopt the modern plan. I am trying to work up an interest, and to get them to take GLEANINGS and get them an A B C book. I think they will come around after awhile. You can consider me your agent here at this place. The future will have to tell how good an agent I am. J. W. ROUSE.

Santa Fe, Monroe Co., Mo., Sept. 3, 1886.

Accept our thanks, friend Rouse, for your kind words, and also for your kindly interest in our behalf. In regard to moths, you have doubtless learned ere this, from the reading of your A B C book, that Italians are a sure preventive of their ravages. We have only one colony in our apiary where there are moth, and this is a colony of black bees which we recently purchased of a neighbor. What shall we do about it? We will give them an Italian queen and a frame of young Italians.

CALIFORNIA.

NOT "A BEE-KEEPER'S PARADISE."

After being in Southern California for three months, and without seeing GLEANINGS, I feel as though I had lost my best friend, and am losing all track of what our eastern bee-keeping friends are doing. Southern California is supposed to be the "bee-keeper's paradise;" but it is far from it in many respects. I have not yet visited any of the large bee-ranches; but from observation, and conversation with experienced bee-keepers, I have concluded that a good location in the East is preferable to this country.

First, though they can probably get twice as large a yield as we can east, yet I think that, with less work, I can make a colony pay better east than here; for here they consider 3 to 3½ cts per lb. a fair price for good extracted honey, while really for the same grade of honey we can usually treble that price.

Second, while California white sage has had a good deal said as to its excellent quality, I have not yet tasted of California honey that beat our pure white clover, extracted, either in taste or beauty. Again, the bee-keepers of this county have had a lawsuit with the fruit-men (especially the grape-men), in which the latter claimed and proved that the bees injured their fruit, and came out victorious. It is said here that the bee punctures the skin of the fruit, without any aid from other insects. If I am not mistaken, most of our leading authorities say the skin is first punctured by other insects.

What do the latest experiments prove? Do they, or do they not puncture the fruit?

The fruit-crop in this part of California is very light this year. Peaches and nectarines were not more than a fourth of a crop, while the orange crop is light. Apricots and grapes are about the only good crops. The people here now are very busy picking their raisin grapes. A. M. PATTEN.

San Bernardino, Cal., Sept. 28, 1886.

Friend P., there is still a good deal of controversy in regard to bees puncturing grapes;

and although they have left our large crop of Concords entirely unharmed, I am satisfied that they have annoyed, and perhaps damaged grapes belonging to our neighbors, when the grapes were left on the vines until after frost, or until they got very ripe. I think the fruit-grower who is also a beekeeper can so manage the gathering of his grapes as to be but little annoyed by the bees; but where people are not ready to gather their fruit when it is dead ripe, and large apiaries are in their vicinity, there is quite a chance of trouble between neighbors.

FRUIT-BLOOM HONEY.

BEE-TENTS, PERFORATED ZINC, ETC.

I SEND you by this mail a sample of fruit-bloom honey. The fruit-bloom honey we get here is good. This year it seems to be better than usual. It is the thickest honey I have ever handled, and it will granulate during the hottest weather. The honey-crop in this section is light, and it may be lighter still before the bees are prepared for winter. This has been a remarkable season. We had much rainy and cloudy weather, but the bees got enough to keep themselves, with some to spare, ever since the first of May. Fall flowers are abundant, and of vigorous growth. My bees, like a great many others reported, seemed to have a swarming fit; but although they nearly all swarmed in less than 21 days, I had no more colonies than before.

USING BEE-TENTS.

We all know how it goes to open hives during a scarcity of nectar. All may go very well if we have nothing more to do than to peep into a colony now and then; but if we have extracting to do, colonies to unite, old queens to be found, and new ones introduced in full colonies, it is altogether another thing. I often use a tent; but when I take the tent away to commence on the next colony, the robbers go for the entrance in a body. Well, I have tried several plans. Last season I struck on a plan that I can depend on. I took an Alley drone and queen trap, and put wire cloth in place of the zinc at the entrance, being sure that it was secure against the combined strength of the robbers. I removed the zinc, or tin slide, from the top. I have used this with complete success during the past two seasons. I find that the robber-bees that get into the hive before the hive is closed come out at the wire-cloth funnels unless the bees kill them; also the bees of the hive can come out if they want to. Of course, this trap is to be removed as soon as the bees are ready to defend themselves.

PERFORATED ZINC.

Last April I got of you two full sheets of your perforated zinc; also a tin-bound perforated zinc honey-board (I would take this tin binding off if I knew the honey-board would be large enough afterward). I cut the two sheets of zinc into honey-boards, and make also 12 Heddon and one Tinker honey-boards to fit the Simplicity hive. They are beveled the same as a Simplicity hive; and when in place they show on the outside and have a bee-space above and below, the same as the Heddon. I like the Tinker, or strips of zinc between slats, best. I should not like to do without these honey-boards, and have to pry and pull to get the frame apart, as I did before this season. I have a simple arrangement to get the honey-board loose from the lower frames very quickly.

Some time ago (July 15th or Aug. 1st) Mr. Muth mentioned something in GLEANINGS about some of his honey having an appearance as though soot were mixed with it. Now, I must always take my surplus honey away from the bees before July 10 or they will mix with it more or less juice from decaying cherries, a small quantity of which will give the honey this sooty appearance when extracted and placed in glass receptacles. Probably this is what is the matter with Muth's honey. I evaporate all honey not ripe by the 10th of July, by running over an arrangement at a temperature of over 100°. 5—W. E. PETERMAN.

Trappe, Montg. Co., Pa., Aug. 19, 1886.

It is true, robbers will sometimes pounce down upon the entrance immediately after the tent is removed. To prevent this would-be pilfering we contract the entrance for the time being so that one or two bees can easily stand guard. Indeed, it is well to keep the entrances of all weak colonies thus contracted during a dearth of honey.—The slatted honey-boards, we should judge from reports received, have doubtless come to stay; in fact, Dr. C. C. Miller, who has just been with us, says he would not now do without them. With the perforated zinc between the slats they will be doubly valuable.—I hardly think the smoky appearance of Mr. Muth's melilot honey was caused from the juice of decaying cherries, and I should be a little skeptical about its coloring your honey in the way you describe.

SOMETHING IN REGARD TO DRONE-TRAPS.

ENTERPRISING CHICKS, AND HOW EXPERT THEY BECOME IN CATCHING DRONES.

THE best drone-trap ever invented is not equal to a dozen half-grown chickens. We feed the chickens in the apiary, and there are about a dozen that never leave it. They eat drones from the time they commence coming out in the morning until they stop in the evening, and some hot days they eat so many drones we don't have them to feed. They became so expert they could catch them on the wing every time, and sometimes two chickens would be jumping up after the same bee. When drones got scarce they began to try a few workers, but didn't relish them, for the workers would sting, even after they were picked to pieces and swallowed. I saw one chicken swallow a dozen drones in five minutes, and then look for more. They also ate a few clipped queens, and seemed to relish them as well as they did drones. They kept the apiary stripped of drones, except in two hives, which were so high from the ground they could not reach them. The chickens were White Leghorns and Plymouth Rocks.

Bees did poorly until morning-glories commenced blooming. The honey-crop is poor in quantity as well as in quality in this county.

W. W. SOMERFORD.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from Sept. 15.

CHAPTER XXV.

By this shall all men know that ye are my disciples, if ye have love one to another.—JOHN 13:35.

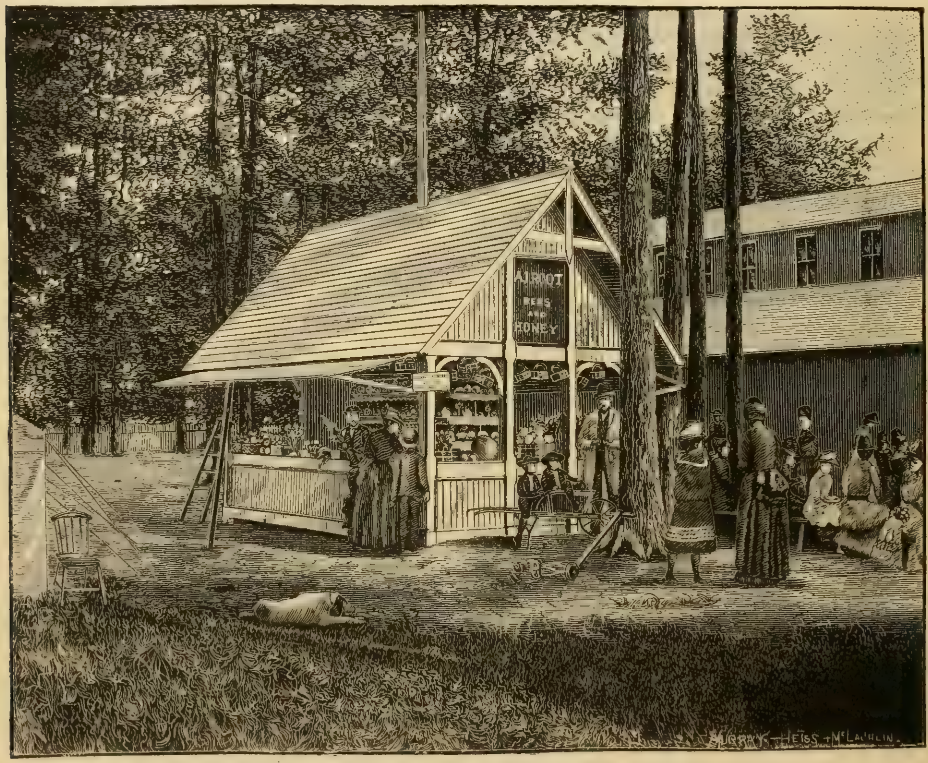
In this chapter I am going to say something about attending fairs—county fairs and State fairs, and I am going to take the position, also, that we ought to go. The friends who have followed me thus far surely know, without my telling them, that I do not approve of horse-racing, games of chance, or gambling of any kind; or betting; neither do I approve of throwing balls at dolls, and getting a cigar every time you throw straight. I am sorry to see these institutions still kept on many of our fair-grounds. I am very glad to note, however, that in many of our State and county fairs—in fact, I think I may say in the most of them—very great improvements are being made in the way of encouraging better morals. The State or county fair now that allows intoxicating beverages to be sold on its grounds is behind the times, and I think a progressive people will very soon give them to understand that such management will not long be countenanced, and that they can not long prosper.

Well, what *shall* we do at our county fairs, you may ask? My reply is, that we should make them the means of receiving and giving knowledge. Let every tradesman and every producer of any crop of any kind go and exhibit his wares; let him stand by them and explain to people all about them. Let us all endeavor to get acquainted with each other, and in this way I think we fulfill the spirit of the little text at the head of this chapter, inasmuch as we can not love people very much without knowing them, at least to some extent. One of the *grand* things to be done in this world is to get acquainted. Staying at home and attending to your own business is all right, if not carried too far. No doubt there are people in every neighborhood who go visiting *too* much; but I think it is equally true that there are almost as many who do not go visiting enough; that is, people who do not meet their fellow-men so as to exchange ideas, and keep posted in regard to the events of the day.

I have, at different times in my life, felt and said that I was tired of fairs; that they were pretty much the same thing every year; that I had no objections to offer, if people wanted to go and enjoy such things, but that I would not go across the street to see all they had to show. Did you ever feel that way, my friend? Well, now, if you have any confidence in my ability to advise, let me tell you that such thoughts are wrong. I believe they are Satan's promptings. You have no right to stay away from all kinds of gatherings, even if you do feel like it. There are duties and responsibilities that fall upon you naturally, and which you can not discharge unless you are among the people and acquainted with the people. If things are managed badly at our fairs, go with the spirit of Christ in your heart and cheerfully take hold of the task of making them better. I am sure the same is true in regard to bee-conventions and class conventions of every description. Besides, in the end it will pay you to go. You may not realize at once that you have been benefited; but, go to your State and county fair; look at every thing that is to be seen; endeavor to understand how different industries are carried on; ask the purpose and use of every thing you see, with which you are unacquainted, and you will, even if you do not realize it at the time, find out afterward that you have acquired valuable knowledge—yes, very valuable. A great many times I see people wasting time enough in accomplishing some desired end to have done it a dozen times over had they known of cheap little implements already in the market for doing this same thing. Many times you pay a hired man money enough for a single week's work to have paid for a tool with which he could have done the same work in one day. Go to your county fair; take along the produce of your farm or the product of your workshop. Explain to the crowds you will meet there how your work is done, and why it is worth the money you ask for it. Let your light shine.

Only a single roadway separates our market-garden grounds from our county fair-grounds, and therefore it is an easy matter for me to exhibit any thing I may have for sale. Last year we made a display of honey; and for the purpose of showing it to good advantage we had a little building put up, which our artist has shown you on p. 816.

You will notice, friends, that there does not seem to be a very large crowd around the building. Well, when the artist came around to take it, there did not happen to be many people around at the time. I guess it was just about time for the horse-races, and so it is mostly women and children who remain around the stand. In the center of the building is a pyramid of shelves. This was mostly filled with cabbages, large ones at the bottom and smaller ones at the top, until the top shelves had some that weighed only a pound apiece. These we offered for a penny. Many of them were the product of the shoots that put out from the stumps after cutting our early Jersey Wakefields. A basket of them was kept on the counter, with a neatly printed card, reading, "Only 1 cent each, or 10 cents per dozen." The counter, clear around the outside, was covered with beets, squashes, potatoes, cucumbers, tomatoes, baskets of peppers, etc. But the particular vegetable on exhibition was "White Plume" celery. This was arranged in celery-glasses, clear around the building. We soon discovered that people were at a loss to understand whether these vegetables were simply for exhibition or for sale, so we put up little boards, saying, "These vegetables are for sale." Another board was put up on another corner of the building, reading as follows: "Some of the products of our Medina clay soil." This was for the encouragement of those who were in the habit of saying that certain things could not be raised in Medina clay.



A GLIMPSE FROM OUR COUNTY FAIRGROUNDS, WITH OUR BUILDING FOR THE SALE OF GARDEN VEGETABLES AND HONEY.

The individual behind the counter, with a package in his hand, is supposed to be your humble servant, and I stayed there the greater part of the three days the fair was in session. I formed, during these three days, many new acquaintances, exchanged new ideas with hundreds of people, and learned some very important and valuable facts by talking with old farmers. At first it seemed rather dull, but I had made up my mind that it was my duty, and I determined to carry it out. I have already told you of the difficulty of selling the products of our modern agriculture. Our ground is now getting in such a state of cultivation that we raise more on a little plot than our whole town can consume; in fact, it begins to be quite plainly apparent, that, on the ten acres we now have under cultivation, enough garden-stuff can be raised to sell in our town of less than 2000 inhabitants so as to amount to between *two and three thousand dollars* yearly, in *cash*. The principal difficulty that meets me now, however, is, that it costs almost as much to *raise* and *sell* the stuff as we get for it; therefore we must reduce expenses by making horsework take the place of handwork; and we must also learn to raise fine products that will command high prices, without very much labor in getting rid of them. Well, the county fair promised to assist greatly in all these points; and by the close of the third day I was very much pleased to find that my plans had been realized. The principal crop sold was the celery, and the "White Plume" celery is just the thing for such an undertaking. When you get any sort of commodity started on the fairground, it sells itself. If a man or woman is seen with a nice bunch of celery in her hand, everybody she meets wants to know where she got it — price, etc.; and by and by, if you do *your* part faithfully, you will soon have everybody on the fairground wanting a bundle of celery. We sold 75 lbs. to the dining-room people, and we retailed enough more to make it toward 500 lbs. Our retail price is 5 cts. per lb.; but to the dining-room people, or anybody else who buys 100 lbs. or more, we sell it for 3 cts. per lb. Cabbages sold pretty well, but the celery was the great staple of our vegetable and honey-stand. Honey is now so staple an article of diet almost every day in the year in Medina that we sold but comparatively little this season.

You will notice baskets hung around overhead. These are a great convenience in any such business. The baskets can be furnished for 5 cts., at a small profit, and a great many times people will buy things if they can get a basket to carry them in, when they would not take them otherwise. Have your baskets handy, and have every thing handy.

We kept paper bags right under the counter, on a shelf prepared on purpose. I learned a great many things in selling before a crowd like the crowd you meet on fairgrounds. One important thing is to be always *busy*. There were three of us taking care of the stand. The man who had charge of the honey kept busy most of the time in filling little glass pails with honey. The woman who assisted employed her spare moments in shelling lima beans. The beans were retailed at 10 cts. per half-pint berry-box full. I was kept busy most of the time in weighing the celery, clipping off dark or discolored leaves, and filling up the celery-glasses. When the contents of a glass were sold, it was slipped into a paper bag; then some more celery was weighed out and put in its place. Many customers came up with a rush, and were in a hurry, therefore I had my paper bags already open, the bottoms pressed out, and every thing in readiness so I could do up the package in a twinkling. You may ask, "Why not have them wrapped up beforehand?" My friends, that does not work well. Customers want to see things, and examine them before the articles are wrapped up. Now, this one thing of being busy is very important. A man who sits down and smokes until purchasers come will not sell half as much as the one who has his coat off and is busy. Somebody says, "What are they at work at down there?"

"Why, they are selling celery like every thing. Just see. They are taking it off just as fast as that fellow can wrap it up. Let us go and look at it."

When they come up to the stand, somebody says, "Where did this celery grow?"

I reply, that it was raised right over the fence, and show them where they can see the white tops of it glistening through the trees. Then come a good many questions; and when people find it can be raised on our soil they naturally inquire if plants will be ready for sale the next spring. I tell them that we always keep strong transplanted plants ready for customers, from the first of April to the first of September. Thus you see our plant-business is advertised.

Then somebody wants to know about Terry's system of raising potatoes. My reply is, "Friends, you can see the potatoes growing right over the fence there, and here is Terry's book, that tells all about just how to do it; and here are some of the potatoes, just as they were dug—no small ones thrown out at all. They come out of the ground just like this."

Now, almost every farmer's boy is interested in nice fruits and in nice vegetables; and especially is he interested when he sees the man behind the counter "just taking in the nickels like every thing," for something that *he* can raise on *his own* grounds. All parties are benefited. The talk in regard to the things is a means of educating the people, and the result is a developing of the resources of our nation, the encouragement of agriculture right around our homes, and especially the encouragement of getting large crops on small areas of ground, thus bringing the whole matter within the scope of people of humble means, and those who have only small homes.

CHAPTER XXVI.

Be ye therefore perfect, even as your Father which is in heaven is perfect.—MATT. 5:48.

Some of the friends may wonder what the above text has to do with raising garden-stuff. Well, I hope I may be able to make it plain that it has a great deal to do with it. At our teachers' meeting recently, the question was asked whether it is indeed possible for *every one* to attain to the *high* graces of Christian life. Is it within the powers of ordinary individuals to lead sanctified, holy lives? I asked the chairman of the meeting to let me talk a little; and when permission was given me to "talk," I told the friends that I felt sure that it *is* within the power of *every one* to lead a life of purity, but that, like almost every thing else in this world, it needed watchfulness as well as prayerfulness. It is as surely possible as it is for one to be proficient, and to excel in business matters. And then I told of some of our trials in getting clerks who could do business without committing annoying and expensive blunders. Our book-keeping, perhaps, requires the most care and precision of almost any one department. When help is needed on the books, we try first one and then another; and may be we get discouraged, and sick of thinking of bringing any *new* help at all, it is so rarely we find somebody who can be trusted. In using the word "trusted" I do not mean that it is difficult to find those who are *honest;* but the great difficulty is to find some one who is *careful*—always careful. The clerk who *credits* a man when she ought to *debit* him can not hold her place very long. She may explain that it was an accident, and nothing intentional; but the world at large nowadays demands accuracy; it refuses to be satisfied without it. Well, at one time I decided that such positions must be given to none but elderly people, say those toward forty years of age. Pretty soon, however, a girl in her teens upset all this philosophy by showing more care and precision than any one who had had any thing to do with the books for a long while, and she did this, too, with only a *few months'* experience. I was astonished to see her go along day after day, doing every thing just right, and doing it in so quiet and still a way that one would hardly know that she was in the room. I began to make it a study to see where the secret lay. For the help of others who had failed I wanted to discover some great truth that might be helpful to the rest. I found it. A great part of her success was because, while at work, she did not take her mind nor scarcely her eyes off from her task. She never spoke to any one unless business demanded it; and it seemed surprising that she could keep the run of things, to the extent she did, and yet ask so few questions. No matter who came into the room, or what was going on, she never looked or seemed to notice. Had an earthquake occurred here, such as the friends had in Charleston, probably she would have looked up and inquired what the matter was; but I rather think, my friends, she would have been one of the *last* to stop her work. You see, she was in the habit of letting nothing divert her from the work in question; and I believe the greater part of the mistakes that are made in this world are because the one who does it was looking at something else, or thinking of something else besides the work in hand.

Now, I do not mean to be partial to the other sex, and I am happy to state that we have boys in our establishment who do just about as well. While age is an advantage, it is only *one* of the elements of success. You may say it is natural for some people to be careful and accurate, while it is not natural for others, and that you have no right to expect it. I admit this; but for all that, the same rules will apply in any kind of life—making garden or driving team. Have your thoughts about you, and bend your whole energies to the work about you; and if you succeed, you *must* do this. Whether you are *hired* to drive horses, or whether the team is your own you are driving, to make a success of your business your heart and soul must be in it. I think our text touches the spirit of the matter. Never stop short of absolute perfection; that is, so far as it lies in you. In spiritual things I think the same rule applies. The question comes up constantly, Which shall it be—self or the honor and glory of Christ Jesus? You are perfectly free to decide which. If you let *self* rule, you may obtain a momentary gratification many times; but if you let the teachings of Christ take the place of selfish feelings, the result will be a full and glorious character. A self-sacrificing spirit will ultimately make your life a blessing to *yourself* and a blessing to those around you; and, if I am correct, most of our troubles come from letting self rule, instead of Christ's spirit. Sometimes it seems very, very hard to put down self and exalt the Master; but it can be done, and must be done. In business matters, also, it is hard, many times, to succeed in making your business pay expenses, especially with the sharp, keen competition that is round about you.

And now I want to point out one more difficulty in making business a success. You will have to strive and work hard, just as you strive and work hard to have a clear conscience, and to be at all times *pure in heart.* You must not let expenses exceed your income; that is, you must not pay out more money than you take in. You may feel like complaining that your lot in life is hard. Satan will tempt you to feel that you are working like a slave, and he may tempt you to revolt, and declare you won't do it, and that you are going to take things easy, as others do. Beware of such thoughts. The *ease* that he holds up to you temptingly is not ease—it is *bondage.* Very likely other folks around you seem to succeed without half the exertion you are making. That has nothing to do with it. I do not mean that you must overtask your strength, for that would be folly. Take such strength as God gives you, and make the most of it you can. But have your wits about you, and keep watch of things. Suppose, for instance, you are obliged to hire a man to plow your ground. Be sure that, when he makes his appearance at 7 o'clock in the morning, every thing is in perfect readiness for him. And, by the way, before hiring a man with a team I would have an understanding as to how many hours he is to work for you; in fact, the better plan is to have him work *by the hour.* If he comes at 7 and works till noon, call it five hours. A man with a good team should be worth 30 cts. an hour, or may be 35. If he is half an hour late, 15 cts. or more is out of *his* pocket and not *yours;* and if there has been an agreement beforehand, there need be no differences in regard to the matter. If he is going to plow, be sure that the plow is in good order, and see to it the night beforehand if possible. You can not afford to pay a man three or four dollars a day to work with poor tools, nor can you afford to have the team stand still while you have him fuss with the tools. Have a good sharp point on the plow, before 7 o'clock. If you are to furnish him his breakfast, be sure that is disposed of before the time to commence. (I believe the women-folks usually *do* see to that part.) Have the plow on the spot also; have the doubletrees attached; see that the clevises are stout; that the pins that go through them are fastened by leathers, or in some other way. I have seen two men and a team stand still a good many times while they hunted and fretted, may be, for a pin that came out of a clevis. If there are any bolts on the plow, see that the nuts are turned up tight. The plow should also be bright. Perhaps the quickest way to brighten it, if it is not kept bright, is to run it through a bed of gravel; and when it is once nice and bright I would give it a thorough greasing with the good cheap lubricating oils we have nowadays. A good big jugful or a canful should be always near at hand. Very often the time of a team can be saved by a little forethought. If you are going to plow, and then draw manure awhile, push the wagon up to the manure-heap by hand, if you can not do any better, and load it while the team is plowing. Keep in mind, that, while a man and team is worth 30 cts. or more an hour, the time of one man is worth only from 10 to 15 cts. an hour; and this one man can very often save the time of two horses and two men. For the same reason, a boy and a man work profitably together. It always makes me feel guilty when I manage in such a way that an expensive man is seen going across the lots after a jug of water. After it happened once or twice, I provided three or four water-jugs. Each jug had a cork in it to keep out insects. I prefer corks to corncobs or any such like substitutes. I also want smooth clean jugs. The hands are carefully instructed to take a jug of water along when they are going some distance away to work. A boy at work with a man will do such errands, and, a great deal of the time, find work that he can do as fast a man could do it. When the boy is not wanted for any thing else, he can busy himself in picking up stones and roots on almost any piece of ground. Whoever manages the work needs to be constantly looking forward to the next job, and to make it his business to see that every thing is in readiness for it. The boy can bring the necessary implements, and have them in place. If manure is to be hauled, the manure-forks can be right at the spot when wanted. Sometimes a teamster will be all hitched up, ready to start, and then have to chase about to find his whip. I find it cheaper to have three or four whips than to waste the time of a man and team in looking after one that may be mislaid. Manage so that the team may never have to stand still while a wagon is being greased. Grease the wagon nights and mornings, or on rainy days. It has been urged, that the team ought to rest occasionally, any way. Very well; rest them by all means when they need rest; but if a team is in proper order, and of the proper heft and strength for the work to be done, they rarely need more rest than they ordinarily get. Another thing: The rest that usually comes when hunting for a whip, or fixing a broken tool, *may* come when the horses need it, and it may *not* come when they need it. If a proper *system* is observed in regard to the work, the rest can be given just when they need it, and at no other time.

My friends, did you never feel like saying that some days were lucky days? Sometimes every thing goes right straight along, and you accomplish a great deal more in a day than you expected; and how pleasantly you feel at night, to think that the tasks and burdens that lay before you have all been properly finished! At other times, every thing seems to go wrong—tools break, get lost, things do not come out right, night comes, and almost nothing is accomplished. The latter are the "unlucky" days. Now, the real secret of it is, good management and bad management. *Sometimes* things come out right by accident, as it were; again, by *accident* every thing comes out wrong. The intelligent and successful manager must take advantage of accidents or unforeseen circumstances; he must also look ahead and be prepared for unforeseen emergences. I presume likely, that, if I excel in any one thing, it is in being able to manage a good many helpers, and have them all pay expenses. I believe the first person I ever employed was my brother; afterward a neighbor's boy, and I enjoyed my first teaching, watching and planning the work for them. I used to enjoy measuring their capabilities. When I could make them profitable, more help was employed. Finally I discovered that girls and women could do many things as well, or better, than boys and men, and so I commenced employing and teaching them. One who has hands at work for him must be constantly using his brains in devising plans for shortening the work. In my daily or almost hourly visits through our rooms and over the grounds, I am continually inventing shorter and better methods. In reading agricultural books and agricultural papers I catch hold of many important hints. Terry's potato-boxes, pictured on page 408, have been a great help; and now I make it a point to insist that every thing that is to be picked up, whether sticks, stones, pieces of bee-hives, or roots and stones in the field, shall be put into baskets or these boxes. We keep a lot of them in the tool-house, and a lot of them scattered over the grounds in different places. If left upside down, the weather does not affect the boxes very much. A few days ago one of the men suggested, while he was digging out stumps, that the piles of roots and rotten wood would make good firewood, and he volunteered to pay the cost of drawing a load of them up to his house, if I thought best. I caught the idea at once, for it is some labor to pile these up and burn them. Well, I discovered that it was quite a little task, even with our small boys to help, to pick up a wagon-load of them, therefore the potato-boxes were brought out; and as the roots were dug from the soil they were tossed into these boxes. When the wagon came around, before I knew it they emptied the boxes into the wagon, thinking they were making a great saving then. But I suggested, "Why, look here, my friends, just set the boxes right into the wagon, and don't pour the roots out until you get to the woodhouse where they are to be stored."

"But we can't get as many into a load," suggested some one.

"But, my friends, you can get on even *more* at a load," and I showed them how to put the boxes on top of each other, so that they rode safely.

Many farmers dig their potatoes and throw them in a heap in the fall, and the same with corn; and I have seen them dig basketsful, and pour them down in heaps in the field; then they are picked up, put into the baskets, and poured into the wagon. When the wagon gets to the cellar they are picked up again, and then poured into the bin in the cellar. When they are sold they are picked up another time, poured into the wagon, possibly, picked up *still* again, and poured into the bin or on the cellar bottom of the purchaser. *Our* potatoes are dug and put into boxes, and we have boxes enough so they stand there in those same boxes until they are to be used, or until they are planted the next April. The boxes are of such a size that they can be set in a wagon without much waste room; in fact, we can easily put on an ordinary wagon all the team can draw of boxes. We draw ours to the tool-house, and place them overhead on boards, separated so the air can pass freely up between the boxes. The boxes, as you know, have openings in the sides and bottom, so that the potatoes are thoroughly aired, while they are kept out of the sun. There they are to remain until the weather is so cold there will be danger of freezing, then they go into the cellar, with the boxes placed far enough apart so they still have air. Last year, our potatoes were put into barrels and taken into the cellar at once; but I soon found they were rotting in the middle of the barrels, while they were all right near the outside and near the top and bottom. Think of the amount of slow, expensive, back-breaking work that can be saved in picking up potatoes by using boxes!

Well, the saving of labor is not all. Think of the injury that is done to fruit — yes, and to potatoes too — by pouring them out so many times, and picking them up. Some farmers use scoop-shovels, and there is a scoop-shovel made on purpose to use for potatoes; but isn't it a great deal better to pick them up just once, and not have them handled any more until they are in the hands of the consumer? I would do the same thing with fruits and vegetables of every kind, as far as possible—have them handled only once. I would put strawberries and raspberries into fruit-boxes, and have those boxes put right into the hands of the consumer, without any pouring or scooping up.

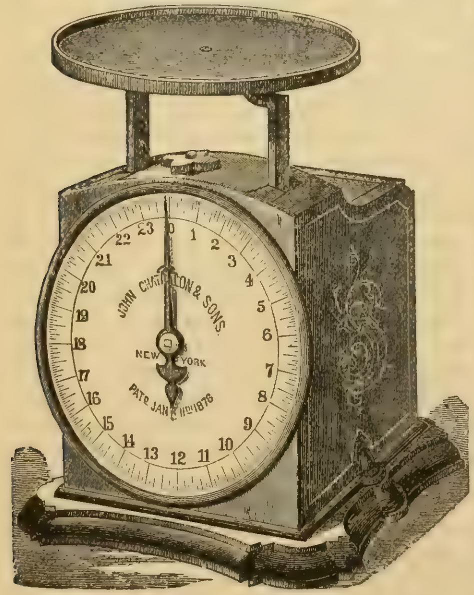
Now, then, in concluding my chapter, which started out with a text enjoining perfection, I exhort you never to stop short of the *best* way of doing things. Don't tolerate imperfect and slipshod ways. Try to do in the best possible way, every thing that is to be done.

CHAPTER XXVII.

A false balance is an abomination to the Lord: but a just weight is his delight.—PROV. 11:1.

The men who go with our market-wagon are Christians, and I do not know but that I might say they are *young* Christians. And let me tell you, my friends, if you have never tried it, there are few better places to test Christian endurance than in going from house to house to sell stuff. Sometimes the best of them complain that it is a wearying and trying business to one's patience. My reply is, "Very likely, boys; but did you never think it is a grand place to show forth the spirit of Christ, and to work for him?" One who can go from place to place, and meet people at all hours of the day, sometimes, as a matter of course, when he is unwelcome, needs to be fortified with a Christian spirit, it seems to me, if any one does. The tradesman who stands behind the counter, needs Christ's spirit too; but he is, in a sense, more independent, because people come to *him;* but in selling garden-produce, on account of the perishable nature of the commodity you are almost obliged to go after your customers.

There are, perhaps, few things in this world that stir up more ill feeling than misunderstandings or dissatisfaction arising from short weights and measures. Our text strikes right at the root of the matter; therefore it behooves the one who sells garden-stuff, to be *just* in his weights and measures. And this calls to mind what I have spoken of before—the very uncertain way in which stuff is sold. Perhaps the most common way with the greater part of the stuff is to sell it by the quart, peck, or bushel; but if you set about it you will find that it is a very hard matter indeed to determine what is a quart, peck, or bushel. When friend Terry started his potato-boxes, column after column was occupied in the *Ohio Farmer* in telling just how large the box should be to hold an exact bushel. If I am correct, it was not settled even then to the satisfaction of all parties. Of course, we know how much a bushel of potatoes weighs, for the law fixes the weight, and so it does that of almost all other produce. But it is not always convenient to take the weight. Potatoes, corn, and apples, are usually heaped up on the half-bushel. Some, in fact, go so far as to say you must put on all you can make stay on. This will do for apples; but when it comes to peaches worth two or three dollars a bushel, most dealers claim that the measure should be only fairly rounded; so you see the quantity purchased or sold is very uncertain indeed. If you buy half a bushel of peaches they are generally rounded up just a little. In transportation they get shaken down so the basket is hardly level full. Now, if you sell them out and heap up your measure there is great danger that you do not get cost for them, let alone the expense of doing business—that is, if you want to sell things on a small margin, and small margins are the rule nowadays—I mean, of course, where you buy the fruit to sell again. We sell fruit on our wagon along with vegetables, to help pay traveling expenses. By the time our wagon had been running about six months, we discovered that by far the better way is to sell things by weight. Look at the market reports in any of your papers, will you? Cabbages are quoted at from three to four dollars per 100 heads. Now, the heads in our field weigh from one to ten pounds. Beets, onions, radishes, asparagus, pie-plant, etc., are usually sold by the bunch. Well, what does a bunch weigh? Sometimes more and sometimes less; and this leaves it for the gardener to give just as small bunches for a nickel or a dime as his customers will stand. Worse still, the bunches are not all alike. Now, we make our bunches by weight. *We* weigh them up, just so much in each bunch. Our cabbages are put on the scales, and sold for so much a pound; the same with celery, squashes, etc. The nicest thing for weighing small quantities is the little scale below.



THE "FAVORITE" FAMILY SCALE.

The scale stands in a convenient corner of the wagon. When the purchaser picks out just the article wanted, it is dropped on the scale, and both parties can see at a glance just what the article weighs. There has been one objection made to this—that a certain squash or melon may be more desirable than the others. Well, our plan is to fix the price at so much for first-quality goods. An indifferent specimen is sold at a less price per pound. Celery is sold the world over, I believe, at so much a root or dozen roots. In our grounds we have a good many roots that weigh a pound each; but by far the larger part of them do not weigh half a pound each. Is not so much a pound by much the fairest way?

Since school has commenced, the small boy we had on our wagon is obliged to attend school, and two men now take charge of the wagon. We have the lines lengthened out so the driver can stand on the step at the back end of the wagon. See cut opposite Chapter XXI. While the driver stands on the seat, his scales are on the low shelf at his right hand, ready to drop any article on them that needs to be weighed. Two men manage the wagon entirely. A trusty horse is used, and a couple of hooks are fixed to hold the lines right at hand on the back end of wagon. Whoever gets through with his customer first, takes the lines and drives along to the next stopping-place. The wagon seldom fails to make a trip on account of the weather. A rubber blanket is carried along to cover the horse when it is rainy. Pieces of enamel cloth of suitable sizes are in readiness to cover articles that may be injured by rain—honey-jumbles, some kinds of fruit, etc. The receipts from the wagon average, in cash, from 50 to 60 dollars per week, going every forenoon. The expense of the trip—men, horse, and wagon, is about $2.00 for each forenoon. Thus you see it costs 20 per cent, or one-fifth of the value of the articles, to sell them; therefore if any one will come and take our stuff from the grounds, in quantities sufficient to gather the crop to order, we can afford to let him have it for one fifth less. We estimate, also, that we can not afford to carry any article on the wagon unless we can make a clean profit of at least 25 per cent; and sometimes even this is too close a margin. Peaches that cost a dollar a basket can not well be sold for less than $1.50 on the wagon.

To be continued Nov. 15, 1886.

HEADS OF GRAIN
FROM DIFFERENT FIELDS.

AN INCREASE FROM 4 TO 26 COLONIES.

ABOUT two years ago I bought two colonies of bees, and had one left in the spring. I also bought one of your A B C books and commenced to study it. That summer I got a queen and ½ lb. of bees of you, and let them out in my empty hive, with one frame of brood taken out of my other hive. They went to work immediately, and did first rate; so by fall I had five colonies, but I got only a little surplus honey. Last spring I had four good strong colonies left, one weak. One died in June. I divided them, and made eight colonies of them; then in about two weeks they commenced swarming. Oh my! how they did act! I had no hives on hand, and had to make them by hand. You can rest assured I was busy. They kept it up until I had 26 colonies before I could stop them. I put three back in the hive they came out of, and tore down the queen-cells, and had two swarms go off. When they stopped swarming they commenced storing honey.

I had about 500 lbs. of surplus comb honey, and have 26 good strong colonies with plenty of stores for winter. E. R. FOSMIRE.

Cromwell, Union Co., Iowa.

GIVING FRESH AIR TO CURE FOUL BROOD.

About June 10th I bought 7 colonies of bees for $1.00 each. They each had foul brood in them in all stages, from larvæ 3 days old to workers nearly ready to hatch. I moved them 9 miles to a new locality, and for 2 weeks the odor from them scented up my whole apiary of 28 colonies. All I did was to go out every night and lift the covers off and pull the cloths from off the frames to give them fresh air. As soon as I commenced uncovering them at night, so the dew could fall on them, they commenced improving, and now there is not a sign of foul brood among them. Two of them superseded their old queens. The two young queens are extra prolific, and all 7 of them are doing well.

The honey crop in this part of the State is extremely small and poor in quality, there being but little basswood bloom. W. W. SOMERFORD.

Navasota, Texas, Aug. 15, 1886.

Friend S., I should be almost inclined to believe that you did not have the real foul brood if you cured them by giving them fresh air only. Perhaps the change of locality had something to do with it. If such were the case, they may have been gathering something in their old locality which brought on and sustained foul brood, and the change removed them from the cause. Or, possibly, as some claim, they got well themselves.

SWARMING AGAIN; AN EXPERIENCE SIMILAR TO G. F. ROBBINS'.

I will now make my report for 1886. I commenced the season with 80 stands, and bought 8 more in box hives for $10.00. I increased to 120, but have doubled back to 112. I took 3000 lbs. of comb and 1000 lbs. of extracted honey. I have sold most of my comb honey at 12½ to grocers, and 15 cts. retail; extracted, 8 and 10 cts. respectively.

The season here opened splendidly with maple and willow, cottonwood, fruit-bloom, locust, and raspberry. All came in in their turn, so that but few of the bees needed stimulating. I have never been able to get the bees to take artificial pollen, probably on account of the abundance of early flowering trees, maple, willow, elm, cottonwood, etc. White clover came on about ten days earlier than usual; and as I was engaged in other business, it found me unprepared for it; but having plenty of materials I soon had surplus arrangements on all, and all went nicely till the first of June, when they took the swarming fever. I shaded the hives and tried to give plenty of room, but swarm they would — first swarms, second swarms, and re-swarms, or those that came out after hiving. One hot Sunday there were 14 of them in all. Often two or three would go together. I would generally hive them together, as I had no time to look up queens, and could find but little help. Well, if you want to know any more, re-read G. F. Robbins' "Fun among the Bees" in GLEANINGS of Sept. 15th. The excessive heat and abundant flow of honey was the cause, I think. The weather turned dry the last of June, and closed the honey season. Spanish needle, though full of bloom, was an entire failure.

I have tried Heddon's plan for preventing second swarms, and have generally succeeded.

Chillicothe, Mo., Sept. 30, 1886. BEN A. RAPP.

THAT CARNIOLAN QUEEN.

I have seven colonies now. I started with two in the spring. They are all in good condition, and are gathering considerable honey, which I will begin to extract in a few days. I have increased two by natural swarming, and three by nucleus.

I bought a Carniolan queen (so called, though she resembled a hybrid) last month, and, observing queen-cells in the hive recently, I put a drone-trap (Alley's) in the entrance, as I am much away from home. The swarm came out a week ago, and clustered in an apple-tree a few feet away.

A boy of 15, who had no experience, managed to get them into a hive after much work, and had them to swarm out once or twice. When I got home I gave them some young brood, foundation, etc.; and though puzzled about the drone-trap and queen, I decided they must have a queen or they would not have swarmed. The queen was not in the drone-trap nor in the parent colony either, so I gave the hived swarm a couple of queen-cells to see if they had a queen or not, for I could not find her. They accepted the cells, proving, I suppose, that the Carniolan queen was lost.

One cell hatched the day following the swarm, while I was looking at it, and the young queen was received. They swarmed out again, however, that day; and as it was a big one I hived it also, making two colonies of the first swarm. Every thing seems to be going on right now, after a week, both swarms having young queens, one of them now laying.

A SWARM COMING OUT IN THE RAIN.

I am quite puzzled how my Carniolan queen could have left the hive with the trap in the entrance, and in what way she got lost. I can not understand why the first swarm sent out another on the following day, and a rainy one at that. They had a clean hive, lots of room, young brood and two cells, yet they came out in the rain at 10 o'clock, and hung on the tree until I got home at 5:30 P. M., when I easily hived them.

It seems to me that after-swarms are always liable to issue if you leave a number of cells in the hive. One of the smallest colonies in which I had been rearing queens swarmed out as soon as the cells began to hatch. I cut the swarm from a tree and let them run into the hive from which they came, and they accepted the situation, and are working contentedly. The first queen can not be depended on to destroy the remaining cells, even when the colony is small. F. M. POTTS.

Media, Del. Co., Pa.

INTERESTING FACTS IN REGARD TO SILVERHULL BUCKWHEAT; THE HONEY NOT DARK BUT LIGHT COLORED.

When I bought those 5-cent packages of European silverhull buckwheat I intended to report whether it turned out well or poorly. Well, for honey the bees work on it the same as on the common. I caught and dissected a bee, and found light-colored honey that she had gathered from it. This made me feel hurrah like; but in a few days after, when passing through a buckwheat-field (I had thought the thing over before, whether *any* buckwheat honey is dark inside of a bee). I opened one, and found the same light-colored honey. Now, why is it dark inside of the hive after they have finished it?

I counted the seed on one stalk, and found 1292, which is near enough to 1300 to call it that; 1300 fold—how is that? If you sow at the usual rate of one bushel per acre you would have 1300 bushels per acre; but these grains are so small that one-half of this amount would be as thick as one bushel of the large would make it; then if you want the yield to be 1300 or even 1000 per stalk, you would have to sow, I should think, about 4 qts. per acre, and take care of it the same as you do corn, which would be—let's see—1300 divided by 8 equals 162½, per acre, which might be done—on paper, at any rate, and could be sold, if sold at Henderson's prices, $5.00 per bushel, for—my! I won't tell, for some one will buy up all the buckwheat and monopolize the whole thing so I shall be left. Now raise your buckwheat on land, and it will be 20 bushels per acre, at 40 cts. per bushel, as this is called a very good yield for this locality; or if you intend to raise 40 bushels per acre you will have to take as good care of it as Henderson does with his, which few do. J. L. HYDE.

Pomfret Landing, Conn., Sept. 27, 1886.

Friend H., I think the reason why the honey was light-colored was because the quantity was too small to show the coloring matter in it. Venders of syrups put their samples in thin glass bottles, and by this means they make a very dark syrup appear very light colored.—I think it would be possible to get an immense crop on a single acre of ground, if the soil were prepared so that it would be exactly suited for buckwheat, and the proper number of plants, and no more, were on each square foot of ground. We are, however, far from such an attainment as *you* mention. The number of seeds you mention on a stalk must have been an enormous product. I do not think I have ever seen any thing like it. We have about two acres of the European silverhull buckwheat, and we propose to offer it for sale at the same price as the ordinary silverhull; or, if you choose, let it take the place of the ordinary silverhull. Forty cents a bushel is lower than I have ever known buckwheat to be sold for in our vicinity. We pay from 75 cts. to $1.00 a bushel, even where we buy 100 bushels at a time.

REPORTS ENCOURAGING.

A REPORT ENCOURAGING, IN POETRY; FROM 14 COLONIES TO 62, and 1700 LBS. OF HONEY.

WILL you permit me to give you the present year's report from 14 colonies, two of which were queenless in April, and had to wait till they raised one, neither of which swarmed nor gave any surplus, except a few lbs. from the brood-chamber? Two others had drone-laying queens, which I did not discover for more than a month, from one of which I got no surplus, but had to stimulate till they raised a queen.

I sold my bees this year,
I kept but just a few;
But fourteen stands and little care,
Increased to sixty-two.

The surplus, too, would seem,
When added up, was found,
Though weighed with care, it kicked the beam
At seventeen hundred pound.

They're ready now for winter, too,
For yesterday I found
Each hive weighs now from sixty-two
To sixty-seven pound.

Of stores, an average
Of one and thirty pound,
Exclusive of the hive or cage
That does the bees surround.

And yet I think they may,
While resting on their oars,
Have fifteen hundred pounds to-day,
Laid up for winter stores.

One colony alone
Gave me three hundred pounds,
And you can choose it when you come,
If better can't be found.

And one, with extra queen,
Two hundred eighty pound;
And biggest swarm I've ever seen,
That weighed about ten pound.

I have no more to feed;
Each hive has now its store,
And six pounds more than each will need,
Or ever had before.

HENRY LARGE, per daughter.

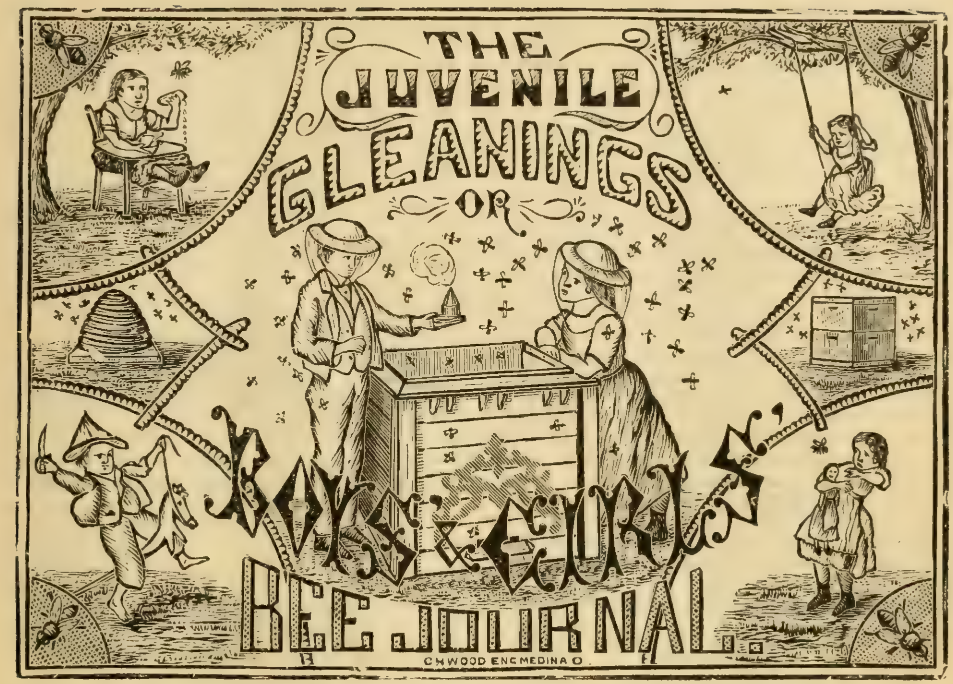
Whigville, Ohio, Sept. 28, 1886.

REPORTS DISCOURAGING.

A BAD YEAR IN TEXAS; SAVAGE CYPRIANS.

TWENTY-ONE years ago I began bee-keeping, and never saw in all this time so disastrous a year as this. I went into winter with 56 colonies of Cyprians in my home yard, and 20 colonies of Italians in my Dresden yard, three miles off. I now have the same number, and not 3 lbs. of honey per colony yet. It has been almost impossible to raise queens, and my queens behave so badly away from home that I am afraid I shall have to quit the Cyprians, in self-defense. Bro. Boomhower stung almost to death, and Bro. Doolittle had to hunt the wood-shed on account of my stinging Cyprians. The April and May drought did the work. In parts of the State, flock-masters (sheep) had to kill the lambs to save the ewes, and some of the flock-masters paid off their shepherds and turned their flocks loose to starve, or be killed by ravenous wolves. In many places in our State, no rains have fallen in from 7 to 14 months. We are not quite that dry here. I have made half a crop of wheat, and one-fourth crop of oats and rye; corn is fair and cotton good, and we may yet get honey.

Dresden, Texas. 21—B. F. CARROLL, 76—76.



He that is faithful in that which is least, is faithful also in much.—LUKE 16:10.

MYSELF AND MY NEIGHBORS.

Blessed are the pure in heart, for they shall see God.—MATT. 5:8.

I DO not believe it is, as a general thing, a good plan to visit our neighbors on Sunday; but there is one kind of Sunday visiting that I have been doing for ten years or more, and I have been so greatly blessed in this kind of Sunday visiting that I like to talk about it. It is visiting the inmates of our county jail. A few days ago I was told that a young man had got into our jail, perhaps to stay many months. I found him in his cell, lying on his bed, sick. I at once thought of the text, "I was sick, and ye visited me; I was in prison, and ye came unto me." As soon as he put out his hand to me and smiled, something flashed across my mind that I had seen him before. He was quite a good-looking young man, dark eyes, and pearly-white teeth that showed plainly when he laughed. Where had I seen him? Years ago he used to come to our Abbyville Sabbath-school, so he told me. He was then but a boy, but now he was a man—sick, and in prison. His temperament was one of those peculiarly happy ones: it is natural for him to be pleased at all times with every thing. He seems to be one of those individuals who see something to be laughed at in almost every feature of human life. Poor Henry! I am afraid, although he did not tell me so directly, that this boiling-over good nature of his —this exuberance of fun, had something to do with his getting into prison. Do you think it strange that a happy disposition can be dangerous? Well, it *is* a little strange, my young friends, but I am afraid it is nevertheless true. Henry's pleasing ways, together with his good looks, I am inclined to think, made him a general favorite; and as he grew toward manhood he got to be a favorite with women-kind as well as men, and this brought him to prison. I can not well explain the details before our juvenile readers here, but I may say this: He had just got married to one woman, when, according to the laws of our land, and the laws of God, he should have been married to another woman. I can easily imagine that a disposition like his might lead him into such troubles. I presume likely he was easily influenced, and may be he was coaxed into something he knew he ought not to do. He was tempted, and gave way to temptation. Had he held fast to the little text at the head of our chapter, and declared in his inmost heart that he would be honest in his heart toward God and his fellow-man, no matter what sacrifice he was called upon to make to keep this purity, he would have been spared this trouble. His natural disposition is to be pleasant and good natured, and he would do almost any thing for the sake of pleasantness and peace—at least, this is my impression of him. But on my second visit, he seemed cast down and discouraged, and in much of a fault-finding frame of mind. He had sent for a doctor, but the doctor did not come, and he was suffering, no doubt, severely. The doctor did not come—nobody came. He even began to complain of his own brother, and of his nearest friends. He felt much inclined to think that the whole world had turned against him and deserted him, and it made *me* feel glad to think that I had remembered him; and although I could not take the place of a doctor, he told me of his mistakes and misfortunes; and although he did not then declare he would choose Christ and his righteousness, I felt that his attitude of heart, when I left him, was something near it.

Now, my friends and neighbors, wherever you are and whoever you are, remember that good looks—yes, even a sunny disposition—may lead you into trouble if you are not careful how you use the God-given gift. I am older than many of you, and I have been saddened by these troubles that have come upon a good many; and let me now, in a closing word of these neighborly talks today, bid you beware how you trifle with these holy relations that ought to exist between man and wife. And let me suggest to our younger readers who have not yet thought much about these holy relations, to beware how they trifle with them in any way. When tempted, just breathe the little text, "Blessed are the pure in heart," and it will carry you safely through all such troubles.

A JUVENILE'S EXPERIENCE WITH SWARMING.

ALSO SOME OTHER MATTERS.

BASSWOOD ended with June; and as it was so rainy during its blooming, it did not produce much honey. The rains kept the white clover going, which is still in full bloom, July 18. Sweet clover, or melilot, grows in acres along the creek bottoms, and it seems to thrive best in gravel and sand banks. The bees fairly roared on it.

Our first swarm came out May 12. It clustered on a bush, was hived on the spot, and immediately moved away, a good piece off, but not far from the old hive. Next morning it came out and began to move off, going slowly and near the ground, in a very straight line, for over a mile. On nearing the woods it raised above the tree-tops, and, after going a short distance, entered a hollow tree that had been before occupied by bees. We then cut the tree, brought them back, gave them a frame of unsealed brood, and they went to work all right. After filling their hive and making 30 lbs. of surplus, they cast a heavy swarm July 1, which now has its hive well filled. Now, do you think the swarm of May 12 sent out a second party of scouts, or did the first party, on returning, find it?

May 26, we had a second swarm come off. It was early in the morning, and the thermometer stood but 60° in the shade. While coming out, thousands of bees fell down in front of the hive. They raised up, and some of them tried to go back, but got into another hive near by. The occupants of the latter rushed out, gave battle, and in a few minutes hundreds were slain. The rest of the swarm scattered out badly, and finally clustered, and was hived on a frame of brood. The next three or four days they fought among themselves and many were killed. Then they went to work. After a while they were discovered to have been queenless, and that they had raised a queen. Do you suppose their queenlessness caused the fighting among themselves?

We had a large first swarm June 23, and it was hived on a frame of brood. It built a considerable amount of comb and honey, and appeared to be all right. The next day it slowly swarmed out, and after a few minutes it began to go into a box-hive swarm. This box hive had got through swarming, and had a young queen at the time, about the age for a wedding-flight. Half an hour before, a young queen was found in front of this hive balled up, and we put her back into the hive. A little later the swarm first mentioned began to move in. Their hive was brought, and as many of the bees as possible were got back by brushing them from off the box hive. But thousands went in, which we never got. Next morning two dead queens were found in front of the new hive, one a virgin and the other apparently a laying queen. The young queen in the box hive must have run out during the excitement the day previous, and was brushed into the new swarm. Both were now queenless. The new hive raised a queen from the frame of brood. A piece of eggs and larvæ was placed in the top box of the box hive, with which they raised queens. Now the question is, Why did the bees swarm out and act so? Could it be that the new swarm had a virgin queen, which, while taking her wedding-flight, fell down in front of the box hive, and that her bees, after finding where she was, swarmed out and followed her?

DRONE ASSEMBLIES.

Last year the drones assembled within half a mile of us. The assembly spread over several acres. I could hear their loud roaring, but could not see them. This year I again found where they assembled, but there seemed to be several assemblies. Two were a quarter of a mile apart.

MILKWEED.

There is a good deal of milkweed near us, and the bees work considerably on it. During its blooming I noticed what I thought to be fighting going on among the bees; but on closely examining them I found out that, instead of fighting, some of the bees were pulling away at the wing-like milkweed pollen on the others' feet; and as thousands of these wings were in front of every hive, I suppose they succeeded in getting them torn off. If this is the case, old as well as young bees can be freed from this wing-like pollen.

A FEW QUESTIONS.

Do bees, when they gorge themselves with honey, while being smoked, ever put it back into the cells again? Does melilot bloom every year? Will swarms that have not quite filled the brood-chamber with comb in the honey-season finish it during fall blooming? CHARLIE L. GREENFIELD.

Somerville, Butler Co , O.

In answer to your first question, I think, Charlie, the scouts that went off while the swarm was hanging on the bush found the hive where you had placed it, and led off the swarm next morning. In answer to your second question, I do not think the fighting was caused by queenlessness, but I do think the *queenlessness* was caused by *fighting*. I think the suggestion at the close of your third query is the right one.—The facts you give in regard to the drone assemblies are valuable. I think drones do congregate thus, and I have no doubt that they sometimes go several miles to form these assemblies.—Bees do put the honey back in the hive after they have gorged themselves on account of smoking; but every time they put it back, there is less of it; therefore every time you smoke a colony of hybrids so as to induce them to uncap their sealed honey, you cause them to lose a certain quantity of their winter stores.—Melilot blooms every year, so far as I know; in fact, I never heard of a plant that was not covered with bloom.—Bees will often finish out unfinished combs during fall blooming.

JUVENILE·DEPARTMENT
F.A.W.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will recive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from $1.00 to $1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

A TALK TO THE LITTLE FOLKS ON PREPARING BEES FOR WINTER.

HOW are those hives getting along, in the back yard? Have they enough stores for winter? If so, are they prepared for the cold with chaff packing? Very likely, many of you have prepared your bees for the cold which is soon to follow; but I fear that *all* of you have not been thus careful, and that you have found it convenient to put it off a little longer. It is to this class of juvenile "putters off" that I am now about to talk. In the first place, I am going to ask, What did you put it off for? One little boy clear over in Wisconsin yells out, "'Cause we don't know how to fix 'em for winter." Another little ten-year-old red-head, with great big freckles on his nose, screams out way down in Texas, "We hain't got no sugar, an' dad says he can't afford to buy none, 'cause bees didn't pay right smart this year, it was so dry." A little girl in the northern part of Maine cries out, "Please, sir, and will you tell us how to winter bees?"

Well, my dear little folks, I do not believe I can; but I will tell you how Sammy and his father in the State of Ohio are preparing their bees. The circumstances run something in this wise:

HOW SAM'S FATHER PREPARED HIS BEES FOR WINTER.

"Say, Sam, what's yer dad doin' with them bees of his?" said Sam's playmate, who lived over across the way.

"Doing with them!" rejoined his companion; "why, he's fixing them for winter."

"What, as early as this, and only — le' me see—the 10th of October? By cracky! I hain't done nuthin' with mine yet."

"You should say, 'I haven't done nothing,'" said Sam, with an air of superiority, evidently shocked at his playmate's grammar, and not knowing that there was still a "mote" in his own eye.

"Oh! nonsense, Sam; you're always taunting me about my grammar and slang. Come! if yer dad is fixing them bees up fer winter, I want to learn how to fix mine." So saying, the boys clambered over the fence into the yard where Sam's father was at work, though Sam stood at a safe distance.

"What yer standing way off fer? These bees won't hurt you," said Jimmy, for that was the name of Sam's playmate.

"No," said his father, when Jimmy explained that he wanted to learn how to winter bees. "Besides," his father continued, addressing his son, "I should like to have *you* learn *too*."

Sam's father, after closing the hive upon which he was at work, opened another. "This colony," said he, "as they have been breeding, needs considerable feeding. They have emptied the bread-pan of feed which I had given them, all in one night." So saying, he lifted off the empty pan. With the smoker in his right hand he gave a few light puffs of smoke, while he slowly pulled off the enameled cloth with his left hand. He next lifted out one of the outside frames.

"Pretty light, and not much honey there," said Sam's father.

The next frame contained still less: the frames in the center of the hive had no honey, but a little sealed brood.

"Sam," said his father, "will you run into the house, and fill this coffee-pot with the sugar syrup I made last evening?"

Sam obeyed, and started for the house.

"Now, don't spill any of it, nor daub the coffee-pot, as you did the other day, when the bees got to robbing so badly," called his father, as Sam neared the house. The bees had got to robbing on that day, and Sam, as a consequence of his carelessness, was stung two or three times; hence his fear on approaching the apiary, for which his playmate taunted him.

Sam quickly returned, and, more than all, the coffee-pot was nice and clean.

"Well done," said his father; "you didn't daub this time."

"N-n-no," said Sam, hesitating; "why,—why, ma poured it for me." His father smiled a little.

"What harm does daubin' the coffee-pot with syrup do?" said Jimmy.

"It is almost sure to start robbing," returned Sam's father; "and wherever the coffee-pot sits, the bees will lick up the syrup, The result is, we have to quit work for the time being."

"Oh!" said Jimmy, "that makes 'em rob and sting. I see. Now I want to ask some more things. How do you feed that stuff to 'em?"

"You will see presently," rejoined Sam's father. So saying, he spaced back the frames and covered them with an enameled cloth, near the center of which the bees had gnawed a hole. The bread-pan was placed alongside of it, and was then filled from the coffee-pot. This done, a cheese-cloth was spread over.

"What's that cloth fer?" said Jimmy.

"That is to prevent the bees from being drowned while taking up the feed," replied Sam's father.

"O-o-oh," said Jimmy. "How much'll you feed that hive—I mean, how can yer tell when they've got 'nuff?"

"I shall feed in this way about 20 lbs. of syrup; or, in other words, until the bees have five or six frames of stores nicely capped over," returned Sam's father.

"But, pa, you won't have to feed all that way," said Sam, who had just now begun to take an interest.

"Oh, no!" replied his father; "a few of my colonies I shall not feed at all, as they have a sufficient amount of natural stores, but a large majority will require a considerable amount of feeding."

"How do you make the syrup?" said Jimmy.

"To 20 lbs. of sugar, add a gallon of boiling water from a tea-kettle."

"That's easy," said Jimmy. "By cracky! if them bees o' yours need feedin', mine do. I must feed 'em to-night." And off he started for home.

"But you won't have time," called out Sam.

"Well, I'll feed 'em to-morrow night, and get the syrup ready to-night," replied Jimmy.

In the next juvenile I will tell you how Jimmy succeeded, or, rather, how he didn't succeed. Ernest.

CHILDREN HANDLING MATCHES.

We give place to the following in this department, hoping that our young friends may read and profit from the results of careless handling of matches.

I had my barn burned, and about 25 tons of nice hay. I had just started my team to hauling the hay to market, and had 4 loads out of the barn. It was a nice new barn, with which I was very well pleased, and every one admired it. The loss will not exceed $600, but it is my whole year's crop, besides the barn, $300.

The way the barn was set on fire is this: We have two little children, and they were playing in the barn, and the little boy found a match somewhere, and the little girl took it and scratched it on the manger. The match broke and flew into the dry hay, and all was ablaze in a twinkle. She tried to carry the fire out, but the wind blew it all back. She then screamed for mamma, but mamma could do nothing then—it was too late. I was away on business. It had not been insured when I left.

Ft. Wayne, Ind. Roland Holmes.

A KIND LETTER FROM A "LITTLE STRANGER."

Mr. A. I. Root:—I am a little stranger, but I don't wish to be one any longer. I would have written before now, but I had nothing to tell you that I thought would be of any interest. Papa is a bee-man. There are but few bee-men in our community. Papa has more bees than any one else I know of in our vicinity.

As every little fellow who writes to you has so much to say about bees, I have concluded to talk on some other subject. I am a little girl, and I love my Sunday-school. I go to Sunday-school regularly, and to prayer-meeting in the evening. I want to so live and act while I am young, that, when I grow old, I may be a useful Christian. I have often said I wished I were as good as you. I am a young member of the church. I intended to read the Bible through this year, but I am afraid I can not do it. Belle Hall.

Sparta, Miss.

ROBBING BUMBLE-BEES.

My brother and I were plowing, and we found lots of bumble-bees, which we kill by taking a little straw, and burning it, and then put it on them and stir them up. One day a little one was hidden in the grass, and he bit me in the foot. When I stepped on him he made me jump. E. Yoder, age 9.

Morton, Ill.

It is just "piles of fun" to fight bumble-bees, I know, little friend, and I used to enjoy it. I presume it is the excitement connected with it which makes it such a favorite pastime among boys. It is just "piles of fun" to tease cats and dogs as well as the poor bumble-bees. But there is a better and less cruel, though, I must acknowledge, less exciting way, to handle bumble-bees. See department of Our Own Apiary, last issue, page 791. I want the boys—yes, and girls too—to report on their success in handling bumble-bees by the plan there prescribed. That is, I want you to show what skill can do. See if you can't astonish your school-friends. Every boy or girl who succeeds by this plan, and promises to fight or tease no more bumble-bees, I will send any thing that may be chosen from the ten-cent counter. Ernest.

HOW A JUVENILE RAISES STRAWBERRIES.

I took a barrel and sawed it in two in the middle. It wants a barrel with two heads. Commence six inches from the bottom to bore holes round the barrel. I bored 17 holes in the first row; 7 inches above that, bore 20 holes. Now put in dirt up to the first holes, then take the strawberry-plants and put the roots in the holes. Take pains to put them in well. Now fill up to the next tier of holes, and put in the plants. Now fill up with dirt, and set the top with plants. It will be best to make one or two holes in the bottom, so that you can not drown them. We have one in our front yard, and it has been a beauty. In the first place, it was full of blossoms, and then full of large strawberries. I should think that two barrels would give one family all the berries they would want. My plants looked nice. Folks stopped and looked at them almost every day. I have orders to make the same. They furnish barrels, and I furnish plants and charge $1.50. G. S. Brown.

Salisbury, Vt.

DIDN'T DO ANY THING BUT SWARM.

I am a little boy. We live 60 miles northeast of Peterborough. My pa keeps bees. He commenced with one colony 4 years ago last spring. This fall we had 20. Last year was a very bad one, and they didn't do any thing but swarm. They filled their hives from the maple in spring, but didn't do any thing with basswood or raspberries. They made some from buckwheat. They did well until last year. ELGIE E. IVES.

Cardiff, Can.

ALSIKE, AND HOW THE BEES WORK ON IT; TAKING DOWN SWARMS.

Papa got an Italian queen one year ago last June, and now he has five colonies from natural swarming. He sowed that peck of alsike clover seed last March that he got of you. The bees were just swarming on it when it was in full bloom. I was afraid to walk through it. He got a fine lot of seed from it too. Papa says that the Italian bee is more industrious than the black bee. Papa values his Italian bees very highly. One swarm went off; and as they were Italians, brother Joe and a neighbor's boy followed them. The bees alighted on a limb 50 feet high. Brother Joe climbed up and tied a rope around the limb, and then cut it off and lowered it to the ground. Then they left that limb and went to another tree. I think they got them down again, but I am not sure; any way, they had to take them three times before they got them to stay down; but they got them hived, and the bees are doing well. CLARA STREBY.

Paw Paw, W. Va., Sept. 16, 1886.

HOW A SWARM ABSCONDED, AND WAS AT LAST RECOVERED.

I am a little boy just nine years old. My papa is a harness-maker by trade. He started in the bee-business two years ago. He commenced with one swarm and increased to 23.

I will tell you about a swarm of bees that went off last summer. When they were swarming, mamma happened to be alone. She ran after them half a mile or more, then she lost sight of them. The swarm was gone two days, then a gentleman of the same town stopped at the shop and told my pa there was a swarm of bees on a small apple-tree in his orchard, and said, "If you go after them you can have them." So pa took his swarming-box on his shoulder, and went where the swarm of bees was. It was about two miles from home, so he shook the bees in his swarming-box, and covered them up with a wet cloth; then he picked them up and put them on his shoulder, and carried them home and put them in a Simplicity hive; and when he examined the bees he found they were his own, that had left. How he could tell that they were his bees was because there were no drones with them. My pa cuts all the drone-cells out in summer. WARREN J. SEITZ.

Clarence, N. Y.

DO BEES TALK?

The following incident was related to me by my neighbor: While examining his bees last winter he found one colony in a starving condition. There was a small cluster of bees in the center of the hive, yet living, but the queen was in one corner of the hive, as far away from the cluster as she could get without leaving the hive. On seeing their condition he gave them sugar, which made them wild with excitement. One bee in particular drew his attention. As soon as it tasted the sugar it ran with great speed to the queen, and, as my neighbor expressed it, bumped its head against the queen's head and immediately started back to the sugar. The queen followed till she reached the sugar, when she gorged herself to such an extent that she died next morning. 5—G. L. JANNEY, 22—38.

New Corner, Ind., Sept. 6, 1886.

The foregoing was not written by a juvenile hand, but I believe friend J. will consider it no disgrace to see his communication among the writings of the little folks, because it bears upon a point we were discussing. We are much obliged for the fact. Is it possible that the little bee, recognizing the starving condition of the colony, knew that, as soon as syrup should be given them, the queen must be fed? And what a queer way of telling her! But she understood it, and it was the bee's way of talking to the queen. I have never yet seen bees signal quite in this way to the queen, or, in fact, to each other. ERNEST.

THE UPS AND DOWNS OF A BOY BEE-KEEPER; HOW HE SUCCEEDS IN SPITE OF REVERSES AT FIRST.

My eldest brother and sister having taken the bee-fever, I took it also. I bought two colonies and an empty hive for four dollars. One of the colonies was in a tree, and the other in a box hive. One day I got my sister to help me, and we went over there, cut the tree, transferred the bees to a frame hive, and got about 15 lbs. of honey, which brought me 10 cts. per lb. I brought both hives home in the fall, and put them where I wanted my apiary.

The next Sunday, Walter's bees discovered the new comers, and turned in and ate up all the honey they had. The Sunday after that, they ran away. I transferred my box hive then; and the Sunday after, they ran away. I was flat in the bee-business then, but still the fever hadn't cooled much. I bought a box hive from Walter for two dollars, and another bee-tree. I cut my tree early in the spring; it had no honey. I transferred into a frame hive, and brought them home, and I also transferred my box hive I got from Walter.

It was a poor spring, and bees ate up all they had, and it looked as if they were going to starve in spite of all I could do. Two or three times I went out there and found them so weak they could hardly fan; but I poured some honey and water on them, and that brought them all right. They managed to live and build up.

Then I thought I must have clipped queens. So one Saturday one of my neighbor's boys was down to see me. I took him out to see my bees, and showed him how I could clip a queen; but she floundered so I couldn't manage her. He then agreed to hold her while I did the clipping. He held her as though he were holding a chicken, and the next morning I went around to look at them and found her on the bottom-board, dead. Well, the bees raised them another queen, and are doing finely. This summer I bought a swarm on a limb. I brought them home in my coat-sleeve. They also are doing well. I have taken about 30 lbs. of honey, extracted. Don't you think this is pretty good for a boy of 14? F. O. SOMERFORD.

Navasota, Texas.

Yes, I think you have done well, considering the "bad luck" you had at first. If you push on in this way you deserve to succeed and will succeed. ERNEST.

TOBACCO COLUMN.

HENRY POWELL has quit the use of tobacco, and requests you to send him a smoker. You can publish his name in GLEANINGS, and I will see that you get your pay for the smoker if he uses tobacco again.

Mineral Point, Wis. REESE POWELL.

I will promise to quit using tobacco in any form. Please send me a smoker. If I ever use it again, in any shape, the man I am at work for will report and I will pay for the smoker, as he is a very temperate man. HARRY CARR.

Goodrich, Mich., Aug. 10, 1886.

I have in my employ a young man 19 years old who has been a constant tobacco-chewer for three years. Under my influence he has been persuaded to stop. It is now nearly a month since, and the hardest of it is over. I told him that, if he persevered, and would promise never to use it again, you would send him a smoker. If he ever does use it I will vouch for the price of the smoker. His name is John Goodhull. C. S. ADAMS.

Williamson, N. Y., Aug. 23, 1886.

BREAKS HIS PLEDGE, BUT HONORABLY PAYS FOR THE SMOKER.

I thought I would write to let you know that I didn't quit chewing tobacco, and I inclose you 70 cts. worth of stamps for that smoker that B. R. Paxson sent for. ELMER DEVENS.

Good Hope, O., Aug. 27, 1886.

We are very sorry to see that you have gone back to tobacco, but we thank you for the honorable act of paying up. We hope you may yet see the error, and pledge yourself never to go back to tobacco again.

THE GRATITUDE AN OLD TOBACCO-USER FEELS TOWARD THIS DEPARTMENT.

I received a smoker from you, with the understanding that I was to refrain from the use of tobacco—a habit which I indulged in for ten years; but I have now decidedly abstained from it, and hope that I shall never feel a desire for it again. I am well aware that my thanks are due to you, and would express them here a thousand times. I am convinced, that if every real Christian would do as much as you to abolish such sinful filthiness, in a few years the weed would be raised no more. I therefore thought to give a mite, and ask you to please send me, for the inclosed, a Dose of Truth. I should like to state to you yet, that I am very well pleased with the smoker; it can't be beat.

New Haven, Mo. TRAUGOTT HERZOG.

KIND WORDS FROM OUR CUSTOMERS.

PROMPTLY TO HAND.

The sections came promptly to hand and are very nice, and I am very glad that you did not have the dovetailed ones to send, as these are certainly very much preferable. ALBERT WILLIAMS.

Sharon, Pa.

ONE TRIP TO THE EXPRESS OFFICE.

The smokers came through all right, both lots of them. They are nice, and I think that the foundation is very nice. It pleases me to have orders filled right off, so that one trip to the express office will do. J. C. MCGREW.

Milnersville, Ohio.

THE BEE-TENT INDISPENSABLE.

Send me one of your latest improved bee-tents. I have used them for two years, and find them indispensable. W. D. WRIGHT.

Knowersville, N. Y.

TERRY'S POTATO CULTURE.

Please find inclosed 45 cents, for which send me Terry's last book. I have his book on potatoes. I am raising some according to his instructions, and it works finely, though we are having a drought. I am pleased with your talks on the "New Agriculture" and gardening. WM. COX.

Viroqua, Wis.

OUR WHEELBARROW.

I received the goods you shipped me last month, and have examined the packages, and find them to be quite correct and very satisfactory. The wheelbarrow is nicer in appearance than any I ever saw, and it will doubtless prove quite serviceable. Its lightness is a great advantage to those who have not a great reserve of physical strength.

The brood-frames and other things in flat are as accurate in fit as could be desired, and the 1-lb. sections are the best I have ever seen.

Media, Del. Co., Pa. F. M. POTTS.

CAN NOT DO WITHOUT IT.

As I am a novice in bee-keeping, I have thought I could not afford to subscribe for more than one bee-paper, and have been and am still taking the *A. B. J.*, and could not do without it, and so, friend Root (as all bee-keepers should be friends), I have come to the same conclusion as to GLEANINGS—I can not do without it. I have only a few colonies—20 in number—at this time; 10 last spring, and 5 the spring before, and I am succeeding so far (thanks to bee-publications and good friends, and especially my best friend, Dr. G. L. Tinker), beyond my greatest expectations. I have taken this year 700 lbs. of comb honey from 10, spring count, and 2 of them were weak. W. S. TAGGART.

Barton, Ohio.

"IN ALL THY WAYS ACKNOWLEDGE HIM."

I have been lent some numbers of GLEANINGS, and desire to express my gratitude to God for the Christian tone and for the witness to the truth it contains. May the good Lord bless you in your testimony to him, and may you ever continue a faithful witness for the truth as it is in Jesus. I fail to see that, in business transactions, all allusions to the truth should be eliminated; for does not the word of God say, "In *all* thy ways acknowledge him"? and in these dark, dark days it is especially needful that our light should "so shine before men that they may see our good works and glorify our Father which is in heaven." I have only lately come here from England with my wife and four sons, and have settled in this country, and I am indeed thankful to know that there is at least one public paper whose editor *is not ashamed to confess Christ.* None of my sons or myself drink intoxicants of any kind, nor do we use tobacco in any form. W. BEERS.

Fayetteville, Wash. Co., Ark., June 1, 1886.

NOT A MISTAKE OF OUR SHIPPING-CLERK.

I appear before you this morning with *hat in hand.* Your faithful packing man was correct about the missing nails, hence I beg pardon of all concerned. I found them snugly hidden in the sections where I did not look, as I took the sections out only as I put them in the frames; and as the rest of the nails were all together in another box, I did not suppose they would be with the separators. I do not count the small pieces, only as I put them together, as I believe you to be *strictly reliable* and correct in your dealings. I will be more particular hereafter. At first I did not like the tin covers; but after putting together and trying them I think them splendid. I wish I had more of them.

Cifax, Bedford Co., Va. E. H. HATCHER.

[Many thanks, friend, for your frank acknowledgment that you were mistaken, and not our shipping clerk. We hope our friends, on reading this, will take note. When they receive shipments of goods from us, and, upon unpacking, *think* they have found something missing, will they kindly continue the search, unpack every thing, and, if the articles are still missing, write us, and we will set the matter right?]

OUR HOMES.

The cup which my Father hath given me, shall I not drink it?—JOHN 18: 11.

EVERY human being, at some time in his life, is compelled to recognize that there is a great unknown world, somewhere behind the scenes, as it were—a world of which we know comparatively nothing. Some unknown power presides in this world, not only calling into existence plant and animal life, but holding in his hand a system of worlds like ours, and wielding them for some purpose of his own. This unknown power has called *us* into existence, for, as it would seem, some all-wise purpose of his own. I believe that most earnest, candid thinkers, also believe that, at death, we are ushered into the presence of this great Being; but it is indeed true, that no one has yet come back from the confines of the grave to tell us what is beyond. We may sometimes catch glimpses of it from the testimony of loved ones when on the borders of the unknown land. But all we get is indeed only a glimpse. I presume many of my readers have often expressed in their hearts a wish that God would speak to us and tell us plainly what are his wishes in certain matters. "Oh that I knew exactly what God the Father would have me do in this emergency!" is a prayer that has often welled up from my heart, and I presume from the hearts of others. I have been told that a young man once wrote a letter to Darwin, asking him if he believed that God had ever made any revelation to the children of men; and, if I remember correctly, Darwin's reply was to the effect that he could not discover that any such revelation had ever been made. I presume likely Darwin meant that there was nothing in the realm of science or natural history to indicate that God had thought fit to break down the barrier that separates us from this unknown world, and stand face to face with the objects of his own creation. Whether or not Darwin meant to ignore the testimony of the Holy Scriptures, I do not know, and I do not propose to discuss the point just here.

Well, now, my friends, *should* God see fit in this present nineteenth century to send a message or a messenger to earth, how would he do it? And if a messenger were sent, how would he make his appearance, and what sort of appearance would he present? Queen Victoria often sends messages to the President of the United States, and may be she sometimes sends messengers. If so, I suppose they come with much pomp and ceremony. They are introduced by dignitaries, and accompanied, probably, by evidences of wealth, refinement, and culture. I believe, however, that the world is not so much given to gorgeous display now as it used to be hundreds of years ago. Kings and queens are human—exceedingly human, sometimes. They are weak and faulty and erring; they make mistakes; they show forth human passions, likes and dislikes. If God should send a message to this world, he would make no mistake. His messenger would probably be without fault or blemish. The question might come up, then, To whom would he probably appear? We here in America would think it proper and fitting that he should first pay his attention to the President, or to the chief rulers of our land. Perhaps, however, some would think it fitting to come first before God's ministering servants, the clergy, and make known to them his wishes in regard to his people. If so, what ministers or what denomination would be first honored by his great presence? Perhaps I am handling this subject awkwardly. I should not be a bit surprised if you thought so, for it is a subject too great for me. It is a subject too great for anybody. The mere attempt makes me feel my utter nothingness. But I do feel as if I had a right, however, to feel satisfied of this: That he would come or send his messenger in such a way as to do the most good to the greatest number. How would he manage to obtain a hearing in this busy world of ours? He might arrest the attention of the people by a series of earthquakes, or mighty thunderings. But after having arrested their attention, would he do most good in that way? If we are going to win our children to righteousness we must come to them with gentle words of love, or we shall be in danger of driving them away and utterly failing in what we wish to do. A father might appall and terrify a child by exhibitions of his enormous strength; but some of us know by experience that "enormous strength" often amounts to but little with a child. Some quite small children will assert their rights, and give exhibitions of a free will. Their disposition is to do as they please, in spite of all the strength that can be brought forward. Many a parent who is not a Christian has perhaps decided in his own heart that it is not by might nor by power, but by a gentle and loving spirit, that he brings his child up in the ways of wisdom and paths of truth.

In the above I have been speaking as a people might speak who have had no knowledge nor conception of the Bible; or, if you choose, a people who *ignore* the Bible. But you will notice that the deduction seems to be that, even if God himself should send a messenger to us, very likely the wisest course would be to adopt very much the plan that we are told he *did* follow, in the New Testament. The one whom he sent, and whom he saw fit to clothe with power, came into the world as you and I did. He lived the life of a little child; he grew up as a tender plant; we are nowhere told that there was any thing particularly comely in his appearance; nobody praised his beauty, so far as I know. As he grew older he was despised and rejected of men. His own brothers, in fact, disliked him. Finally he was a man of sorrows and acquainted with grief. One of the infidel writers says he went through the world a disappointed man, succeeding in gathering only a small handful of humble followers. He did not go near kings nor princes; he made no display, except the miracles which he performed to prove to mankind that he was sent by God the Father. These miracles themselves, however, were of a humble kind. Although the power was vested in him of producing earthquakes, beyond any thing the world has ever yet seen, he never used that power. Only once or twice did he command the elements, and even then it was simply to say to the winds and waves, "Peace be still." He might have chosen an occasion for this great wonder, when kings and princes, and multitudes of learned men were present. He did not see fit, however, to do so, but chose the night time, when he was alone in the middle of the sea, with only a few humble fishermen near him. Instead of doing grand and startling things, he confined his works mostly to the healing of the sick. It seemed, however, to be God's purpose to give a succession of miracles, each one a little more wonderful and startling than those that preceded it. It has sometimes seemed to me as if the class of unbelievers who followed him around had been saying, "Oh, there is not any thing so wonderful about this, after all. The storm may have been ready to stop at just about the time he spoke, and these sick people may have been already mending. Who knows but that they would have got well themselves?" If such were the case, however, God's plan seemed to meet all such skepticism, for pretty soon he raised to life one who was dead. It was only a widow's son, however, and only a comparatively small circle of mourners were present, for it was near a small town or hamlet. He might have brought to life the son of a king or queen; but God, in his infinite wisdom, seemed to feel that, if he came to the lowly and humble, the great could easily stoop down and meet him, or avail themselves of his teachings, if they chose. Had it been the other way, and his work been directed to the great and mighty, how ready the humbler class would have been to say that it was all very well, but that it was not for *them!*

Well, now, if God had planned a succession of miracles, what one should be the great masterpiece or culminating wonder of that whole life? We, in our feeble human knowledge, might have thought there would be wisdom displayed in stepping, from such a lowly and humble life, up and up toward grander things, until the finishing touch should be something that would rend the very heavens, and unveil to mortal gaze the dazzling splendor of the gates to the eternal city. I mean to suggest, that men of the world might have planned it something that way. Please excuse me if I seem to be irreverent. I mean simply to contrast human wisdom with God's wisdom. After that wonderful miracle of raising the widow's son, it is true, a greater one followed in the same line. Lazarus, after having lain four days in the grave, until even his sister feared that his body might not be fit to look upon, or be near, was bidden to come forth; and we afterward read of Lazarus being present at a dinner where the Savior was. After this, can we wonder that his disciples looked expectant toward some greater and grander display of his power? So certain were they that it was going to happen ere long, that they quarreled among themselves as to which one should be entitled to the highest rank when these things should come to pass. It is true, this quiet humble messenger of God told them repeatedly they were mistaken, and that no such grand things were going to happen; but, human-like, they would have it that he should be made king. Who else in this wide earth was in any respect qualified to be such a king as he might be? He was the one whom God intended to be king, without question, and they reasoned much as we would, that the world would soon see it, and they would make him their king any way. The world did catch a glimpse of his kingly attributes, and at one time they followed him, throwing down branches of trees, and spreading their garments in the way, and shouting, "Blessed is he that cometh in the name of the Lord! Hosanna in the highest!" But it did not last long. Jesus was not stirred nor puffed up by these demonstrations. He felt more like weeping; and, in fact, he had wept over the folly and wickedness of humanity. God revealed to him that he was marching to a cruel death, and that this death was to be the final triumph of his ministry here on earth. None of them could comprehend the wisdom and loving kindness of this, God's plan for the redemption of the human family. Jesus seemed to be alone, and deserted by all the world. His most faithful and earnest followers were not only making a sad blunder, but they rejected the very idea that he should die, the victim of the hatred of evil men. When he tried to tell Peter that it was best that he should thus die, Peter vehemently declared that it should not be so. I can imagine how sad and disappointed Jesus felt to see that his most earnest and vehement friend and follower utterly rejected God's plan. When he again and again tried to tell this little band of followers of the beauty of such a life of sacrifice, they either were utterly unable to comprehend it, or they entirely rejected it. When they were disputing as to who should be greatest, he asked them if they were able to drink of the cup that he should drink of. They promptly replied, with awful and almost brazen confidence, that they were able; and one of these two was the "beloved disciple." When the time came, however, they were appalled at the thought of this terrible sacrifice, and all, or nearly all, fled in dismay. It was beyond the comprehension of humanity. It has sometimes seemed to me, that, if Jesus could have had the sympathy and consolation of one single friend and follower at this time, his task might have been by far an easier one. At the mount of transfiguration he was cheered and encouraged by the presence of Moses and Elijah, and we are told that they conversed with him in regard to this very matter. Who knows but that they were strengthening him for this very ordeal? He was not only human in suffering, as we are, but he was tempted by Satan as we are. Satan tempted him in the wilderness forty days, but Jesus came out triumphant. He bade Satan get behind him. It seems, however, that Satan still hung around, and probably all through Christ's life on earth, or until very nearly the close of it. It was probably

Satan who whispered to him that it was a piece of folly, and quite unnecessary, when he prayed in the garden that the cup might pass from him; but when the prayer was not granted, Jesus was able to say, "Nevertheless, not my will, but thine, be done." After this struggle with temptation, I can imagine that Satan left him; but I am inclined to think, however, that he came back during these last agonies. Perhaps the fiery fiend was near with his taunting suggestions when Jesus breathed those last words, "My God, my God, why hast *thou* forsaken me?"

Now, I have reason to think, dear friends, that it is quite likely Satan will try to tempt and torment us, even up to our very last moments. If the Savior was called upon to battle with him, why shouldn't we? This is true, however, and may God have the praise for it, that the same grace that carried Jesus through will carry *us* through. For a long time it has seemed beyond my comprehension why God's plan must include this terrible and agonizing torture. Why should God plan for his only son a death by human hands that strikes us with horror? Again I feel my weakness, and again I feel how utterly unfit I am to try to grapple with this great subject; and yet, as I study these closing words of our Savior, a grandeur and glory begin to unfold themselves to my comprehension, such as I have never seen before. God wants us to be strong and brave; therefore, in giving us a model life to pattern ours by, it must necessarily include a life of courage and bravery and self-sacrifice amid awful suffering. We are called upon to endure hardship in suffering here in this world. Yes, for some reason that we can not understand or comprehend, it seems to be necessary for us to learn to endure suffering; and the question that confronts us is, Shall we shirk it and evade responsibilities and trials, or shall we face them and learn to take them with Christian-like fortitude and courage?

We are finally getting close to our text, dear friends. Peter was going to deliver the Master by fighting. He was acting out just what he said some time before, that these things should not be; and even if all the rest of the disciples had fled, frightened by the mob and soldiers, he was going to give them to understand that *he* was ready to fight, even if he had to fight alone. He could not get the idea out of his head but that the Master needed fighters. Jesus seemed inclined to let them go on, without any effort whatever to escape the impending violence —"As a sheep before her shearers is dumb." Peter deemed it a good deal easier to fight than to be trodden upon. He was one of those people who vehemently declare they are not going to be run over and trampled in the mud by any man. After all Christ's teachings, after all his examples, Peter had no glimpse of a Christ-like spirit. Jesus said, "The cup which my Father hath given me, shall I not drink it?" Peter said, by his actions, "No, we are not going to submit to any thing of that sort." Poor Peter! what a breaking-down and humbling of that haughty spirit there came a few hours later! Peter's fault, however, was more of the head than of the heart. He had no deliberate purpose of doing wrong. There was no cup for *him* to drink which he was rejecting. He seemed unconscious of the fact that there was a good deal of wicked pride in his heart, and that he needed some great lessons in humility. The cup was a hard one for the Savior to drink, just as many of our cups are hard for us. For a time he felt as if he could not go through with it. But the better spirit at length triumphed; and after the triumph he speaks of it as his glory. "Now is the Son of man glorified." And the glory that he alludes to is the ignominious death on the cross.

I presume, dear friends, that you and I will be called upon to pass through terrible trials—trials that will make our flesh creep, and perhaps our beating hearts stand still. Then comes the awful question before us, "The cup which my Father hath given me, shall I not drink it?" Some of us will perhaps say, "I can not, I can not." And perhaps we shall turn away and give it up. What then? Why, if we have let inclination rule instead of a sense of duty, we have started in the Devil's service, and the end will be the bottomless pit. I do not know what these trials will be, nor in what shape they may come; but I believe they come to all of us. May be the appetite for strong drink comes over you as it never came over you before. Perhaps you lie awake, tossing in torture because of Satan's promptings and suggestions. It may be terribly hard to bear; but, my friend, you will simply be tried as the Master was tried. "The cup which my Father hath given me, shall I not drink it?"

My recent visit to the jail, mentioned in Our Neighbors, suggests another form of temptation. Suppose you know it to be your duty, before God and before man, to take one of the opposite sex to be your companion for life; but over and against this duty, suppose circumstances are such that you love another, and that the way is open before you to do as you choose. I know it is a terrible thing to be united for life to some one you do not love. Satan whispers to you, that you had better die first than make such a sacrifice. The recording angel suggests that *duty* is the path of peace, even though it should include *death* in reality. The one course may seem to you to be a whole life of self-sacrifice; but through this life of self-sacrifice, Christ the Savior may be by your side. The other course seems to offer you the greatest happiness you can conceive of, for personal inclination can appeal tremendously hard, as I happen to know. But there can be no Christ with it—no Bible, no religion, no God. Well, it is a sad fact, my friend, that there are thousands who do choose to follow inclination, even though it cut off God and heaven, and the peace that the Savior can give. Now, when you come to such a crisis as this, just read over this text —"The cup which my Father hath given me, shall I not drink it?" Go down on your knees, ask God to help you do your duty, and go forward. Take up the cross, and follow him; and let me whisper to you, by way of encouragement, that by and by that cross will be found easy to bear. Perhaps some of you may think, that, because I am getting old and well along in years, I am forgetting how hard it is to give up some earthly idol. No, I am not forgetting, but I am glad of an opportunity to tell you that these things are, many of them, but fancies —fancies pictured by Satan, most probably. You may imagine you really *love* some one of the opposite sex who is untrue. and even impure. My friend, believe me when I tell you that it is only a foolish, silly notion. The truest, holiest, purest, and happiest love that ever blest man or woman, was a love governed by reason and common sense, and sanctified by the spirit of Christ. This false fabric, built up by the Devil himself, can be brushed away almost as easily as you could brush down cobwebs. All that is needed is the spirit that the Savior breathed in our little text—"The cup which my Father hath given me, shall I not drink it?"

You may be in anger; you may feel for days and even weeks as if revenge would be the sweetest morsel that the world has to offer; but duty says, "Never mind; let it go." And Jesus says, "Do good to those who hate you." An opportunity comes for doing good to this person who has persecuted you. You stand undecided. The old struggle comes up, and you wonder whether it is right for you to do any thing so revolting to your feelings and inclination. Remember how the Savior bade Peter put up his sword, and stood silent and still while they put upon him the crown of thorns and the purple robe. "The cup which my Father hath given me, shall I not drink it?" None present could see or realize that his glory was approaching, save God the Father. And, my dear friend, the glory of your life is waiting for you when you fight these battles and go through these struggles, providing the prayer of your heart is, "The cup which my Father hath given me, shall I not drink it?"

Perhaps you feel glad, or have felt glad, to labor for Christ in foreign lands. Your education has prepared you for it. You step forth in the vigor of manhood, fresh from college. Opportunites are offered you for a brilliant career in business or among the professions. The companionship of cultured and intelligent people is dear to you. The luxuries of wealth are very dazzling and enticing. Your taste for the things you have prepared yourself for through the labor of years may seem, for the time being, to have gone; and again comes the question, "Shall we follow taste and inclination, or shall we follow duty?" It seems hard to bid adieu to loved ones, to forego the pleasures that seem to fall naturally to the lot of your friends and associates. What would Jesus say, under the circumstances, were he in your place? "The cup which my Father hath given me, shall I not drink it?" Your life, perhaps, may bid fair to be a life of toil and privation, or of hardship; perhaps you lack sympathy, and may be you do not even receive kind words; but your duty demands that you stand where you are, and try to brighten the life of some relative, may be, Perhaps that relative is unthankful—may be bitter and sarcastic. May be your whole soul revolts at the imposed bondage, and yet your *duty* lies there. May be the very ease which you coveted—things which you have prayed for, are before you, and you have but to say the word and all is yours; but the probabilities are, that Christ must be left behind if you accept. What encouragement is there for you to waste your life in this way? The encouragement of the example set us by the Master. "The cup which my Father hath given me, shall I not drink it?" Suppose you take these words with you; suppose you say them over and over again to yourself, as you go through the busy cares of life. Do you think it beyond possibility that just these words alone may make these duties joyous? I tell you, my friend, they are the words of life. If you cling to those words, and rejoice at the opportunity of sacrificing for his dear name's sake, your battles are mostly over. Satan flees in dismay; and even though your lot is a humble one here on earth, and among things earthly, glimpses of that great unknown beyond, and of the glory that awaits all who delight to obey and love his holy name, shall be your portion. These words have brought me so much happiness of late that I have learned to associate them with a beautiful little hymn, a verse of which I wish to give you in closing:

Sing them over again to me,
  Wonderful words of life,
Let me more of their beauty see,
  Wonderful words of life.
Words of life and beauty,
  Teach me *faith* and *duty;*
Beautiful words, wonderful words,
  Wonderful words of life.

OUR OWN APIARY.

OR, RATHER, A TALK WITH DR. C. C. MILLER IN REGARD TO TOPICS CONNECTED WITH THE SAME.

A CARD from Dr. Miller announced the pleasing intelligence that he would stop off at Medina on his way to the convention at Indianapolis. On the evening of the 9th he arrived at the Home of the Honey-Bees. The Monday following I seized the opportunity to learn from him many of the little "kinks of the trade," as well as his opinion on the more important issues connected with bee-keeping. While we were standing in the office I remarked to Dr. Miller something in this wise:

"Let's proceed at once to the apiary, where we can there witness the operation of the various devices as well as discuss them. Besides," I continued, "I wish to learn from you a great *many* things while you are here."

A moment more and we were on our way to the apiary, when, opposite the engine-house, the doctor said:

"I should like to see your new engine."

In a moment more we were looking at it.

"A fine one indeed," said the doctor, as I proceeded to explain the principle of the new automatic cut-off.

"You see," said I, "this engine is quite different in appearance. The governor is located on the main shaft, and is connected with these two eccentric-rods, one of which works inside the other, accomplishing what is called the automatic cut-off, and the steam-chest—"

"Yes, that is *very* nice," said my friend, abruptly, with a twinkle in his pleasant eye, as I proceeded with an elaborate explanation; "but," he continued, "time is *very* precious."

"Certainly," said I; "it is *bees* we were to talk about," and glancing at my Waterbury, which I had forgotten to wind, I intimated mechanically that time was flying.

A moment more, and we were walking down one of the aisles.

"By the way," said friend M , "I did not succeed in making that sawdust fuel you spoke of in GLEANINGS work in my Clark smoker."

"Is that so?" I remarked, a little surprised. "We have no trouble with it whatever. I will light my smoker now, that you may see just how we manage to make it run half a day."

By this time we had arrived at the house-apiary door. When inside I showed him the keg containing the sawdust.

"Ah! I see," said my friend. "*Your* sawdust is very different from mine."

"How so?" I queried.

"Your sawdust," he continued, "is more like my shavings, which I use in my smoker. That is, it is stringy—more of a spongy character, and will not pack so solid as mine."

While he was speaking I proceeded to fill and light my smoker. Having dropped in a few pieces of rotten wood, I sent several squirts from the oiler, and in a twinkling had the wood ablaze. I explained that it was necessary to convert these few chunks of rotten wood into coals. I then dumped in a few handfuls of sawdust. "Now," said I, "this smoker ought to run for half a day." I worked the bellows, meantime, vigorously, but no smoke. I continued, but no smoke. Dr. Miller first looked amused, and then laughed in his quiet way. On the contrary, I grew a little nervous, and explained that "I had never had it do that way before." The doctor then told a little story illustrating my case, but I'll not tell it here. I found that, in talking, I had omitted to work the bellows while dumping in the sawdust. I emptied out the contents of the smoker on the ground. I then filled as before, but was more careful to keep the bellows working while I dumped in the sawdust. The result was, I had a good volume of smoke. "Now," said I, "that ought to last four or five hours," which it did, giving a good volume of smoke.

Dr. Miller then explained that he thought he had something superior to the kerosene and the little oiler. To about a gallon of water he adds a pound of saltpeter. Into this mixture he throws his rotten wood. The wood absorbs the liquid, and on drying it holds the saltpeter in its fibers. This, he explained, pushed into the shavings which he uses, will light and hold fire.

"How long do you make your smoker run without refilling, when charged with shavings, and the little piece of prepared wood for holding the fire?" I asked.

"That depends—about an hour generally," was his response. "But," he continued, "it is no trouble to recharge at the expiration of the time. I keep a supply of shavings in a covered box near the center of my apiary; and whenever I happen to go by said box, and my smoker needs filling, I dump in a few handfuls, and go on about my work."

DRONE-TRAPS.

Just at this time the apiarist came into the apiary to commence work. When he came up where we were talking I handed him the smoker I had just filled.

"By the way," said the doctor, when the apiarist had left us, "I should like to see one of the Alley drone-traps."

"Oh! yes, sir," said I. "Here is one on the shelf, and also one of the Batchelder."

The doctor then explained that he had apiaries located out from his home, and that it sometimes happened, during the swarming season, that it was three or four days before he and his assistants could get to them.

"Now," said he, "do you think the Alley trap, from your experience, would catch a queen when the swarm issued, and keep her alive three or four days?"

"I think not, as the trap is now constructed. Four or five hours, possibly a day, would be as long as she would live," I replied.

I then explained that there was a little device for letting the queen go back into the hive, when the bees, discovering her absence, had returned.

"But that is not what I want," said my friend. "The queen for me must be kept alive in the cage for three or four days." After discussing it for awhile, and referring the matter to "A. I.," it seemed at least feasible that the queen might be thus kept after the swarm had issued.

I then attached one of the Alley traps to a chaff hive, that the doctor might see how the bees behaved. As I have, in a former issue, explained, the bees on returning seemed a little confused. While we were watching, a number of said bees passed the trap without any apparent difficulty, and with pollen adhering to their legs too.

About this stage of proceedings father came out and announced that Barney (the boss printer) said they were "all out of copy," and that I must proceed forthwith to my desk in the corner. I left the doctor to take care of himself, and did not see him again till noon.

At the noon service friend Miller gave us a few choice selections of his songs, rendering them in his own good way. I will say, for the benefit of a few of our readers who may not know, our machinery stops promptly at 11.50 A. M., and the hands assemble in the large office. During the ten minutes we have a brief noon-service, at which time the hands join in singing, after which the editor of GLEANINGS reads and talks, ending in a short prayer. For Dr. Miller we had the machinery stop five minutes earlier—something we do not do very often. The doctor threw his whole soul into his music, and I think I never heard such an appeal for Christ through the medium of song as our friend gave us in those 15 minutes.

CELLAR VERSUS OUTDOOR WINTERING.

In the afternoon, when friend Miller and I were together again, the subject of wintering came up.

"I wish," said the doctor, "that you were going to winter a few colonies in the cellar."

"But why winter in the cellar, when we have been obtaining such good results on the summer stands? Besides, it takes more brains to winter indoors. The matter of cellar temperature and ventilation is a problem in itself. Then there is the lugging in and out."

In reply to this, friend M. said that those wintered in the cellar did not as a rule require half the stores of these wintered on their summer stands, and that as regards the lugging back and forth, to and from the cellar, it cost him for hired help about one cent per colony. On a moment's reflection, I saw that cellar wintering would save about 50 cts. per colony on the supposition that it would save about ten pounds of syrup; the syrup I called worth about 5c. But friend Miller, in order to secure proper ventilation, as well as temperature, heats his cellar with a hard-coal stove. I forgot to ask him what part this played in the expense, but I presume that he would say that would be overbalanced by the expense of chaff hives in out-door wintering.

"But," said I at length, "I don't believe we have suitable accommodations, as the cellar which we built for the purpose under our new house has steam-pipes connecting radiators in the room above. At any rate, suppose, friend Miller, you take a look at the cellar, and as you have had experience in this matter, you can advise us."

We went together in company with the apiarist to look at the cellar—a large spacious one with heavy stone walls supporting the brick building above.

"Why," said the doctor, on carefully surveying it, "this would be a capital place."

"But the steam-pipes?" I interposed.

"I think they will cause no trouble," he replied; "besides, with the exception of one or two, they are covered up. A little heat from the pipes will be an advantage. You know I heat my cellar with a stove to bring about proper ventilation. Why, yes, you ought to try a few here for the sake of GLEANINGS."

"Do you really, then, think they would winter here?" said I, brightening at the thought.

"I don't *know*, of course, but I *think* they would; at any rate, you can try," he answered.

"But there are no sub-earth ventilators, such as you have described in GLEANINGS," said I.

"You won't need them, if you put only a few colonies in the cellar by way of experiment," said he.

"I believe, then, if nothing prevents I will try four or five colonies, and report in GLEANINGS," I replied.

On our way back to the factory we began to discuss supers, hives, reversing, etc., but I shall hardly have space to go into details here, though I may occasionally refer to them in future issues.

In justice to Dr. Miller, I will state that the conversation related is not strictly verbatim, yet sufficiently accurate, I hope, to preserve the true shade of ideas.

In conclusion I desire to say, if Dr. Miller will pardon the familiarity of his junior in age and experience, that he is a "grand good fellow," and, better than all, a true follower of Christ. He did not make me to feel at all that he was one of the "big guns" on bees, and for that reason my conversation with him was more free. I believe I never yet fully realized the benefit derived from the interchange of ideas in regard to the subject of bees with a brother bee-keeper. I gleaned many a little fact from our friend, which I could not have obtained from conventions or bee-journals, though I do not in the least depreciate the value of either. These "*un*conventional conventions," as W. Z. Hutchinson has fitly put it, are just what bee-keepers need. In fact, my friend W. Z. will remember that I had with him one such a visit some three or four years ago. I would say, then, brother bee-keepers, get together more; and while you recognize the value of these large conventions, do not ignore the little ones where "two is company and three is none."

ERNEST.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER.
MEDINA, O.

TERMS: $1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, OCT. 15, 1886.

I pray not that thou shouldest take them out of the world, but that thou shouldest keep them from the evil.—JOHN 17:15.

HONEY-JUMBLES.

WE are now able to furnish you a barrel of those nice honey-jumbles for an even $5.00. There are from 45 to 50 pounds in a barrel, and a dozen and a half cakes make a pound, as a rule.

NO MORE QUEENS.

FROM J. P. Moore we have received the following card:

> Please tell the brethren in your Oct. 15 issue not to send me any more orders for queens until next spring, as my season's stock of queens is exhausted, and I am still receiving orders which I can not fill. J. P. MOORE.
> Morgan, Ky., Oct. 11, 1886.

A CORRECTION.

ON page 781 of our last issue, I was in error in supposing that our friend C. C. Miller reflected on publishers and supply-dealers, as our readers will notice by a careful reading of his article. If the doctor will accept my apology, I will try to be more careful hereafter.

A BOOK ON CELERY CULTURE.

THE best thing we have been able to get hold of is a little book of 15 pages, by W. W. Rawson, Arlington, Mass. The book is advertised at 25 cts.; but by purchasing 100 copies, we are enabled to furnish them for 15 cts. If wanted by mail, add one cent extra for postage. It gives full particulars in regard to storing for winter, as well as cultivation.

THE AMERICAN APICULTURIST.

I BELIEVE we have omitted to notice that this journal is now in the hands of our old friend Henry Alley, and so far it seems to be managed with much credit to him. The October number contains articles from Prof. Cook, G. M. Doolittle, Charles Muth, Heddon, and others. As these all write on the subject of wintering, it makes this one number of considerable value.

THE SOLAR WAX-EXTRACTOR.

IN our recent articles on the above, we have omitted to mention that the credit of the invention belongs to O. O. Poppleton, formerly of Williamstown, Ia., who recently moved to Florida. Friend P.'s description and illustrations will be found in GLEANINGS for September, 1883. From the description there given, it seems likely that friend P. used it, even before any of the friends who have mentioned it in California. We have also omitted to give credit in our A B C book, but it will be credited in the new edition, now on the press.

DISCOUNT ON GOODS ORDERED FOR NEXT SEASON'S USE.

DURING the month of November, the discount mentioned on page 755, Sept. 15th issue, will be changed to 8 per cent instead of 10 per cent. Remember, if you want the *10 per cent* discount, get in your orders before November 1.

BUCKWHEAT, ANOTHER USE FOR IT.

ABOUT the time our European silverhull buckwheat began to fill out with grain, one of our hens which had stolen a nest brought out a large brood of chickens. In a few days more another did the same, and then a third. Now, these three broods of chickens have not had a bit of care or attention. We should think they would average ten or a dozen chicks each; but they are so spry in the buckwheat that I have never been able to count them. Here we have three broods of blooded stock that cost absolutely nothing in the way of expense for food, or time and attention, and yet I think not a chick has been lost. Now, why will not those who make a business of raising poultry sow patches of buckwheat at intervals, expressly for the fowls and chicks? If the poultry-raiser be a bee-keeper also, he can raise a crop for his bees and poultry, and the one does not conflict with the other at all, neither is there any expense in harvesting the honey or the grain, providing just about enough be sowed for the fowls and no more.

CONVENTION NOTICES.

Nebraska bee-keepers will meet for their next annual session in Lincoln, Neb., on the second Wednesday in Jan., 1887.
H. N. PATTERSON, Sec.

The Southern Ill. Bee-Keepers' Association will hold its next meeting at Benton, Franklin Co., Ill., Thursday, Oct. 21, 1886, at 10 A. M.
F. H. KENNEDY, Sec.

The annual meeting of the Western Bee-keepers' Association will be held in Pythian Hall, corner of Main and 11th Streets, Kansas City, Mo., Oct. 27, 28, 29, 1886.
P. BALDWIN, Sec.

The semi-annual meeting of the Central Michigan Bee-Keepers' Association will convene in Pioneer Hall, at the Capitol Building, in Lansing, on the third Tuesday of October, at 10 o'clock A. M.
J. ASHWORTH, Pres.
Lansing, Mich.

ILLINOIS CENTRAL BEE-KEEPERS.

In consideration of the meeting at Quincy, Ill., on the 19th, 20th, and 21st of Oct., at the laying of the corner-stone of the Soldiers' Home, the Executive Committee of the Illinois Central Bee Keepers' Society have postponed the yearly meeting at Mt. Sterling, Ill., from Oct. 19th and 20th, to Nov. 24th and 25th. The prospects for a grand success are certainly good, as many active and prominent apiarists and specialists have signified their intention to be present. The meeting will be held at the Court-House, and hotel accommodations are good. We are negotiating with the landlord for rates at the City Hotel, which we think will not exceed $1.00 per day.
J. M. HAMBAUGH, Sec

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

Six hybrid queens at 25 cts. apiece, or the lot for $1.25. C. F. UHL, Millersburg, Ohio.

Two mismated Italian queens to spare at 40 cents each. CHAS. MCCLAVE, New London, O.

I have a few fine hybrid queens at 30 cts. each, by return mail.
W. A. SANDERS, Oak Bower, Hart Co., Ga.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ad's intended for this department must not exceed 5 lines, and you must SAY you want your ad. in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates.

WANTED.—Beeswax. Any amount of average beeswax, at 22 cts., cash on delivery.
E. T. LEWIS & CO., Toledo, O.
17tfdb Apiarian Supply Dealers.

GREAT BARGAIN.—2 printing-presses, 50 fonts of type, cases, rules, leads, etc. Cost about $300; will sell for $125. But little used.
19-20d W. EARLE CASS, Roseland, Essex Co., N. J.

25 STANDS of Italian bees for sale in new chaff hives at $7.00.
20-21d JOHN C. STEWART, Hopkins, Mo.

A GRAND OFFER. Pure Italian bees in new two-story L. hives, only $5.00. I guarantee safe arrival, and 30 lbs. of honey. For particulars, address
20d S. F. REED, N. Dorchester, N. H.

WANTED.—To exchange my Given fdn. mill, good as new. I will take honey, or good winter apples for it. L. BECKWITH, Berlin, Wis.

TESTED Italian and Carniolan queens at $1.00 each, to close out my surplus stock. Italians crossed with Carniolans, 2 for $1.00. Or I will exchange for high-class W. Leghorn chickens.
20d CHAS. D. DUVALL, Spencerville, Mont. Co., Md.

WANTED.—To exchange strawberry-plants, six varieties, for untested queens.
20-21d J. A. GREEN, Dayton, Ill.

WANTED.—To exchange for extracted honey, 5 chaff Eclectic hives, just as good as new, or for cash, at $2.00 each—a bargain.
20-21d F. HOLTKE, Carlstadt, N. J.

ITALIAN QUEENS, tested, $1; hybrid, 3 for $1.
18-20db N. ADAMS, Sorrento, Orange Co., Fla.

WANTED.—To exchange pant cloth and black waterproof cloth, for pure Italian bees. Samples will be sent to any address for offers.
20d T. DREW, So. Hanover, Mass.

THOROUGHBRED FOWLS, 14 different and distinct varieties—will exchange chicks for full colonies of Italians—must have sufficient honey to winter. XLCR POULTRY YARDS, Mt. Vernon, O.

WANTED.—Honey, extracted preferred, in exchange for hives, frames, section boxes, saw-mandrels, and bee-hive machinery. What have you got, and what do you want for it?
20tfdb D. S. HALL, So. Cabot, Vt.

WANTED.—To exchange 17 acres of good land, Lewis Co., Ky., for Italian bees in Simplicity hives. Forty good colonies take the land if in 30 days. Address L. B. POLK, Selden, Fayette Co., O.

WANTED.—To exchange for cash, or good horses and mules, 200 colonies of bees in Simplicity frames; also 40 acres of land adjoining the city.
20tfdb ANTHONY OPP, Helena, Phillips Co., Ark.

FOR SALE or exchange.—One French buhr millstone for grinding feed, 18 inches in diameter; as good as new; will sell for half price.
20d H. L. RICHMOND, St. Johns, Mich.

FIRE! Fire! Fire! Brother bee-keepers, you all want my LIGHTNING FIRE-KINDLER, costing about the same, almost as necessary, and but little more trouble, than matches. Perfectly safe. No litter. Time, temper, and match saving; household convenience. It makes a fire immediately. Lasts a lifetime. Sent by mail for 20 cts.
20tfdb S. S. BUTLER, Los Gatos, California.

DADANT'S FOUNDATION

is asserted by hundreds of practical and disinterested bee-keepers to be the cleanest, brightest, quickest accepted by bees, least apt to sag, most regular in color, evenest, and neatest, of any that is made.

It is kept for sale by Messrs. A. H. Newman, Chicago, Ill.; C. F. Muth, Cincinnati, O.; Jas. Heddon, Dowagiac, Mich.; F. L. Dougherty, Indianapolis, Ind.; Chas. H. Green, Berlin, Wis.; Chas. Hertel, Jr., Freeburg, Ill.; Ezra Baer, Dixon, Lee Co., Ill.; E. S. Armstrong, Jerseyville, Illinois; Arthur Todd, 1910 Germantown Ave., Phil'a, Pa.; E. Kretchmer, Coburg, Iowa; Elbert F. Smith, Smyrna, N. Y.; D. A. Fuller, Cherry Valley, Ill.; Clark Johnson & Son, Covington, Kentucky; J. B. Mason & Sons, Mechanic Falls, Maine; C. A. Graves, Birmingham, O.; M. J. Dickason, Hiawatha, Kan.; J. W. Porter, Charlottesville, Albemarle Co., Va.; E. R. Newcomb, Pleasant Valley, Dutchess Co., N. Y.; J. A. Humason, Vienna, O.; G. L. Tinker, New Philadelphia, O., J. M. Shuck, Des Moines, Ia.; Aspinwall & Treadwell, Barrytown, N. Y.; Barton, Forsgard & Barnes, Waco, McLennan Co., Texas, W. E. Clark, Oriskany, N. Y., and numerous other dealers.

Write for *samples free*, and price list of supplies, accompanied with **150 Complimentary** and *unsolicited testimonials*, from as many bee-keepers, in 1883. *We guarantee every inch of our foundation equal to sample in every respect.*

Foundation - Mill For Sale.

One ten-inch Root comb-mill, second hand. The mill has, however, been completely fitted up, painted, and varnished, and is, to all appearances, both in looks and quality of work, equal to a new one. Price $15.00. The list price of a new mill of this kind is $20.00. **A. I. ROOT, Medina, O.**

4 H.-P. ENGINE FOR SALE.

A Bargain for the man who is in need of a First-Class Engine and Boiler.

This is one of B. W. Payne & Son's Eureka engines, the same that we advertise in our catalogue. It has run 3 months since it was new; has had a 10-foot galvanized-iron smoke-stack added, and is in perfect running order. The man who is holding it had to put in a larger one to meet the demands of his trade. The price of a new engine and boiler complete, no stack, is $275.00; but to make a quick sale we will sell this one with the stack for $225.00, free on board cars at Higginsville, Mo.

CONVENTION NOTICES.

Nebraska bee-keepers will meet for their next annual session in Lincoln, Neb., on the second Wednesday in Jan., 1887.

H. N. PATTERSON, Sec.

The Bee-keepers' Association of Hamilton and Tipton Counties, Indiana, will be held at Westfield, Saturday, Nov. 6, 1886. All interested in bee-keeping are invited to come. Bring your baskets well filled, and stay all day, and help make this one of the most interesting sessions the Association ever held.

ILLINOIS CENTRAL BEE-KEEPERS.

In consideration of the meeting at Quincy, Ill., on the 19th, 20th, and 21st of Oct., at the laying of the corner-stone of the Soldiers' Home, the Executive Committee of the Illinois Central Bee Keepers' Society have postponed the yearly meeting at Mt. Sterling, Ill., from Oct. 19th and 20th, to Nov. 24th and 25th. The prospects for a grand success are certainly good, as many active and prominent apiarists and specialists have signified their intention to be present. The meeting will be held at the Court-House, and hotel accommodations are good. We are negotiating with the landlord for rates at the City Hotel, which we think will not exceed $1 00 per day.

"Little ✦ Detective"
SCALE FOR $2.00.

This is the same scale that we have sold for years at $2.50. It weighs from ¼ oz. to 25 lbs., and does it so accurately that they are used largely by postmasters in weighing letters. What can be handier for weighing out small lots of honey than one of these? They weigh 10 lbs., boxed ready to ship, and we can sell them for $2.00; with a tin scoop, 50 cts. more; with double beam, $3.00; tin scoop added, 50 cts. more. If sent alone, they will probably go cheaper by express.

A. I. ROOT, Medina, O.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or $2.00 per annum, when given once a month, or $4.00 per year if given in *every* issue.

$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or $2.00 per year.

Those whose names appear below agree to furnish Italian queens for $1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable. Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for $1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

" dark - - - - -	4@5
" white sage, California - -	5½
" amber " - - -	5
Beeswax, - - - - - - -	20@22

Oct. 23, 1886. CLEMONS, CLOON & CO.,
Cor. 4th and Walnut St's, Kansas City, Mo.

BOSTON.—*Honey.*—Honey is selling well, but would sell better if weather were colder. No change in prices. BLAKE & RIPLEY,
Oct. 22, 1886. 57 Chatham St., Boston, Mass.

MILWAUKEE.—*Honey.*—The market here is firm on choice quality of comb honey in sections, also on extracted. Choice white 1-lb. sections, 12½@13; choice white in 2-lb. sections, 12@12½. Dark, not wanted. Extracted in bbls. or ½-bbls., choice, 6½@7; extracted in tin, 7@7½; dark, in bbls. and ½bbls., 5@5½. *Beeswax*, nominal, 25c. A. V. BISHOP.
Oct. 22, 1886. 142 W. Water St., Milwaukee, Wis.

NEW YORK.—*Honey.*—There is a first-class demand for comb honey, especially for the finer grades. We are almost daily receiving shipments of various discriptions and quality. We make no change in our quotations. We have no demand whatever for extracted buckwheat honey owing to the fact that California extracted white and amber honey is selling at very low figures.
Oct. 22, 1886. THURBER, WHYLAND & CO.,
Read and Hudson Sts., New York.

CINCINNATI.—*Honey.*—There is no change in the market, worthy of note. A fair trade is done in comb honey, and small packages of extracted honey for table use, while the demand is slow from manufacturers. No change in quotations. Extracted honey brings 3½@7c on arrival, and 12@15c is paid for nice comb honey in a jobbing way. There is a good demand for *beeswax*. We pay 22c per lb. for good yellow. CHAS. F. MUTH & SON,
Oct. 21, 1886. Cincinnati, Ohio.

CLEVELAND.—*Honey.*—The market has not improved in the past few weeks; sales are very slow at 13@15c for best 1-lb. sections of white; other grades almost unsalable at any price. Extracted dull at 6 cts. *Beeswax*, scarce at 25c.
Oct. 20, 1886. A. C. KENDEL,
115 Ontario St., Cleveland, O.

ST. LOUIS.—*Honey.*—We note a better demand for choice white-clover honey in 1-lb. sections. It sold readily to-day at 13@14c. Good honey, Spanish needle, etc., 12@12½ in 1-lb. sections. Extracted and strained honey, no change. California holds us down. We are offering white sage at 5c, and amber at 4c in cans, by carload lots.
WESTCOTT & HALL,
Oct. 22, 1886. 108 and 110 Market Street.

FOR SALE.—White clover and basswood honey. Extracted, at 7c in barrels holding about 370 lbs. each, on cars here, and no charge for the barrels. In 5 and 10 barrel lots, will pay freight to any place under 300 miles. Also several barrels of a darker grade that we will sell at 6c. Our honey is thick and nice. E. FRANCE & SON, Platteville, Wis.

FOR SALE.—5000 lbs. of extracted white clover and basswood honey, in oak iron-bound barrels, holding about 370 lbs. each, delivered on board of cars. Price 7c. Also a few barrels of dark at 6c. No charge for the barrels.
PHILIP H. FELLOWS, Brodhead, Wis.

40-Horse-Power Engine for Sale.
Our new automatic cut-off 90 horse-power engine is now driving the machinery in all our buildings. Now, we want to dispose of our old 40 horse-power engine which has done such faithful work for us for the last eight years. It is a standard plain engine, Lord & Bowler make, 12x20, with a 9-foot balance-wheel and a 6-foot fly-wheel. We will offer it, put in good repairs, for $350.00. We will throw in the stone upon which the bed-plate is bolted, free of charge. For further particulars, write us. Whom shall we hear from first?
A. I. ROOT, Medina, Ohio.

Recent Additions to the Counter Store.

KIND WORDS FROM OUR CUSTOMERS.

Inclosed find $1.00, for which please send GLEANINGS. It is like doing without tobacco to do without GLEANINGS. ALLEN BRYAN.
New Sharon, Ia., Sept. 30, 1886.

The goods shipped by you on the 9th came to hand all right. I am delighted with the wheelbarrow. It is a "daisy," and no mistake. I tell you, it astonishes the natives. S. A. STRIKER.
Manchester, Va., Sept. 30, 1886.

Goods arrived. Every thing is satisfactory, especially the lawn-mower. I could not have bought one of that size here for less than $10.00. It works very well. J. A. GREEN.
Dayton, La Salle Co., Ill.

A SCHOOLTEACHER'S OPINION OF GLEANINGS.

I am glad, indeed, that you are in the supply-business, for I am certain that, in no other way, could you afford to give so much reading-matter for a dollar. I have been a printer, and know about what so much matter costs. May success continue with you. I wish to express my sympathy, too, for your troubles with foul brood. May it never return to your apiary, is undoubtedly the earnest wish of your 6000 readers. With a school of 400 scholars to look after, I still find time to manage my little apiary of 26 colonies. Z. T. HAWK.
Denison, Ia., Oct. 15, 1886.

NORTH-AMERICAN CONVENTION.

A Few "Pointers."

RENDERING BEESWAX.

MANY persons spoil wax by melting it in dirty iron kettles; also by overheating it, or, when using steam, by admitting the steam into direct contact with the wax. Wax may be rendered in an ordinary boiler upon a stove, by using plenty of water. A sack of wire cloth sunk in the boiler will enable any one to dip the melted wax from the inside of the sack in a tolerably fair state of purity. The solar wax-extractor is destined to take the place of other wax-extractors. There is no expense for fuel, the wax is of superior quality, and the honey in cappings is saved. A small solar wax-extractor is preferable to a large one. It should be of such size that the wax placed in it will all melt in a day. The dish containing the melted wax that has run from the extractor ought to stand in the sun, in order that the wax may remain in a melted state, allowing the impurities to settle. The heat of the sun is never sufficient to injure the wax, but the honey has a flavor of pollen.

SEPARATORS.

Mr. N. N. Betsinger, of New York, has, for four years, been using wire cloth for separators. The mesh is four to the inch, and the cloth is dipped in molten metal, which fixes the wires solidly in their places. The bees can pass very freely, while the wire acts perfectly as a separator. Mr. B. uses a case for holding the sections in such a position that the separators remain a bee-space from the sides of the sections. Mr. Betsinger has patented his invention.

FOUL BROOD.

This subject was quite largely discussed. Good evidence was introduced, showing that the disease may be spread by means of honey. It was also thought that many people did not correctly interpret the published descriptions of foul brood. The descriptions given are applicable to the advanced stages of the disease; but when it first starts, only a few diseased cells will be seen, and there will be no noticeable odor unless the nose is brought near the foul brood. When a larva is diseased, its color changes to that of coffee with milk in it, and it will stretch out (if a pin be thrust into it and an attempt made to remove the larva) to the length of an inch. It finally assumes a darker hue, shrinks and dries up, and remains upon the lower side of the cell, where it resembles a speck of tar. Several had cured foul brood by the starvation plan.

HONEY-PLANTS.

The advice at present is to raise such plants for honey as will yield something besides honey. For this purpose, alsike clover stands at the head; next comes buckwheat, then rape and raspberries. The most promising plants to raise for honey alone are sweet clover, figwort, spider plant, and the so-called Chapman honey-plant. The latter is a biennial, resembling a thistle. The seed is sown in the spring, and, after the plant is fully established, it requires no further attention. It yields honey in very large quantities, has a fibrous stalk that some one thought might be utilized in making straw paper, and 2½ lbs. of ground seed has furnished 9 ounces of fine clear oil.

DRONES AND DRONE-COMB.

Drones serve no purpose except the fecundation of queens, and bees build drone-comb only when they wish to rear drones for the fertilization of queens, or are building combs for storing honey during a good honey-flow. The majority of those who had tried hiving swarms upon empty frames did not favor the practice; they did not secure so much honey, but *did* secure too much drone-comb. A few had succeeded to their entire satisfaction.

Rogersville, Mich. W. Z. HUTCHINSON, Sec.

QUEENS' VOICES.

CALLING IN THE CELLS.

IN Oct. 1st No., page 778, E. S. Miner takes issue with me in regard to queens calling while in the cell. Prof. A. J. Cook said, some years ago, that, when the first young queen hatches, if the *bees* intend to send out a second swarm we hear this peculiar note of the queen, and she is *answered by the other queens still in the cells* (italics mine).

I have heard them calling when I knew there was no queen in the hive outside of a cell, and when the cell-cap was not cut loose so the queen could push her head out, as suggested by Bro. Root. I cut a queen-cell out of a hive where five or six were calling, and heard the young queen call in the cell while I held it on my knife, and the cap was not cut partly off. I laid the cell down to take out some frames, and in about five minutes she came out. I cut out all but one cell, and at night the queen had quit calling, but still the bees swarmed next day, leaving the old colony queenless. I used the cells and queen that hatched, to form nuclei. I ask Bro. Root to say whether young queens ever call in the queen-nursery. I never used one. Why does the first young queen begin to call before leaving the cell, *only* when the bees intend to swarm, if not because she is kept in by the bees? When one calls, the others answer. At other times the oldest queen hatches, and the other cells are destroyed without any quarreling among the queens.

I ask Bro. Miner to examine carefully a cricket, grasshopper, or other insect that makes a similar noise, and he will find it is made by the covering of the wings, provided with a special apparatus for that purpose. And no insect that I know of makes a similar sound with the true wings, or without this special provision. The worker-bees make several variations of a buzzing, or humming sound, with their wings; but it is very different from this piping of the queen. There is no way of proving positively that the queens do this calling, because kept in by the bees; but it is a fair inference, when at such times the queen will stay in the cell until old enough to fly, unless taken out of the hive, when she will come out at once, and at other times come out without calling, looking like a worker just hatched, and unable to fly. This is my conclusion after three years' investigation to find the cause. 9—JOHN C. GILLILAND, 15—25.

Bloomfield, Ind., Oct., 1886.

Friend G., I can not remember that I ever heard a queen call while in a cell in the nursery. I am glad you suggest the matter, for I do not remember to have ever thought of it before. I should like to hear from friend Hayhurst and others who have used the nursery a good many years.

CALIFORNIA.

BEES IN AN OLD DUNGEON.

YOU may remember me as a former resident of El Dara, Ill., and, while there, a bee-keeper. I came to this country a year ago this fall, partly for health, and also to escape the hard winters. I find it a delightful change, and an improvement in both health and climate. I intended to go into the bee-business here, but instead I have been buying and selling. This is the most wonderful country for bees I ever saw. They never winter-kill; spring dwindling is unknown. Bees work the year round. Honey is very cheap. I got the finest extracted I ever saw, almost transparent, and of good body, for 3 cts. per lb., and retailed it for five; beautiful comb honey in 2-lb. sections, at 6 cts. per lb., and sold it for 8 and 10 cts. My zeal for handling bees has rather oozed out since finding honey so low and abundant.

Wild bees can be found among the rocks and in caves in the canyons here, some having been there for years, with immense quantities of honey. And, by the way, I want to mention one little fact that is wonderful. I went out with a party the other day to the old Jesuit Mission, about 4 miles from here. It's an old adobe and brick structure, over 100 years old. The main building, bull-pens, arches, and wings, cover several acres, or did. Much is in ruin now. Well, in one wing, running out from the main building, there has evidently been a dungeon; but above this room there seems to be space for another room, though I could find no entrance, nor any sign of there ever having been; but there are three different sides where bees are passing out and in; two entrances are very strong. The air seemed to be full of bees, and they keep up such a roaring you can hear them for rods away. In looking over this old pile, viewing its rude but grand architecture, its ornamental work, images, etc., now fast crumbling away, I was filled with wonder and delight; but when I came to the department of bees I was moved within me as *never* before. There must be within that wall quite a large room. The guide tells of their having bees there for 20 years.

Now, Bro. Root, come out and visit this wonderful State. We will go up to the old Mission, get permission from the authorities, dig a hole into that wall, and just take out that honey, bees and all. You can load a car and take it right home.

GLEANINGS comes, a welcome visitor. I like to keep watch of the progress made by our old friends in managing bees. Extracted honey here is put up in square tin cans holding 5 gallons each, and two cans in a case, the two just sliding in nicely; then they are nailed up.

The weather here by the coast is wonderfully cool — mercury standing at about 80, sometimes dropping to 70. T. C. BUNKER.

Oceanside, Cal.

Well done, old friend; but why don't you dig a hole into that unexplored room, without waiting for me to come and help? I think my brother at San Diego will be the man for the undertaking. He is always ready for adventures. But I can not understand how it is possible that this room should have remained all these years without being explored. It seems to me something like the age of the world when people lived so many centuries on one side of a vast ocean, without enterprise enough to get across and see what was on the other side. No disrespect intended to you, friend B.

SELLING THINGS BY WEIGHT INSTEAD OF BY THE BUSHEL.

W. J. Green, of the Experimental College (Columbus, O.), Gives us some Valuable Facts in the Matter.

ALSO SOMETHING ABOUT RAISING STRAWBERRIES IN THE FALL.

NEARLY all vegetables and fruits vary greatly in weight at different times of the year. The size of individual specimens that make up a given bulk affects the weight considerably. There is also much more difference in varieties than is commonly supposed. A bushel of "Peck's Pleasant" apples weighs about 55 lbs.; but the same bulk of some sorts weighs not more than 45 lbs. Peerless potatoes weigh more than most other sorts. White onions are usually not so heavy as red or yellow.

I give you below the legal weight per bushel of vegetables, fruits, etc.

Irish potatoes, -	60 lbs.	Onions, -	50 lbs.
Sweet "	50 "	Tomatoes,	56 "
Beans, shelled,	60 "	Turnips,	60 "
Peas, "	60 "	Apples,	48 "
Dried apples,	22 "	Peaches,	48 "
" peaches,	33 "		

A bushel, as applied to fruits and vegetables, is a very indefinite quantity, and ought to be abandoned as a standard. There is no possibility of settling upon a given bulk or weight for a bushel that will be satisfactory and fair at all times. If we agree upon the weight of a bushel, and establish it by law, as has been done, then there will be a variation of from 5 to 20 per cent in the cubic contents. If the other course were taken, and we agree upon the cubic contents of a bushel, then there will be the same variation in the weight.

The best thing that our legislators could do for us in this matter would be to repeal the law, and thus leave us without a legal bushel for fruits and vegetables. We should then take the only course left, and sell by weight. This would do away with "false bottoms" and many other easy ways of cheating. If it did not make people honest, it would at least make dishonesty more difficult. The only class that are now benefited by the legalized bushel are the dealers. They buy by weight when they find it to their advantage to do so, and it often is, but to the great disadvantage of the grower. These same dealers retail, not by weight, but by measure, which often gives them a fine profit, even at the same price per bushel at which they buy. The consumer might, of course, demand a legal bushel, but he seldom does so. In cities, a large share of the fruits and vegetables are sold by hucksters, and nothing better for their purpose could possibly be invented than the bushel measure and its fractional parts. They can make a bushel and a half out of 60 lbs. of potatoes, without the least difficulty, and with little fear of detection.

STRAWBERRIES IN THE FALL.

The strawberries that you saw in Indianapolis were probably grown near that city, although they might have come from New York, or, more likely, from Tennessee or some other part of the South, where it is not uncommon to grow a second crop. We have here at Columbus a small second crop almost every year, of some varieties. Occasionally the product is sufficient to pay for picking and marketing; at least, such a thing has been done near here. The Cumberland Triumph is the variety for the purpose, as it is almost the only one that gives us any quantity of fruit in the fall. The essential condition to produce a second crop is, that the plants shall have almost a complete rest after fruiting, for a month or more, and then be brought into vigorous growth. When a drought occurs during July or August, succeeded by a warm wet September, we may expect plenty of Cumberlands in September or October

If you do not wish to trust to nature to give you a second crop you may get one in a small way by artificial means. If you should force any strawberry-plants in the greenhouse for early berries you can use those same plants for a fall crop by simply keeping them dry for a few weeks during the summer, and then force them into growth again. Doubtless other ways might be devised to accomplish the same ends, but I will trust you, Mr. Root, to find out ways and means, if you *want the berries*.

Columbus, O. W. J. GREEN.

Friend G., I am very much obliged indeed for the facts furnished. I notice that the matter has been pondered by wiser and more experienced heads than my own; but I do think we should do every thing in our power to have our weights and measures so they will discourage attempts at fraud. I hope it is not true that all hucksters are as unprincipled as you mention, but I very well know that many of them are. It seems to me the adoption of weights, instead of bushels, will be a very great advance, and I do wish it were possible to adopt the decimal system of weights and measures, when we once get about it. When I adopted the plan of selling celery by the pound, I supposed we had got at something definite, so as to make it fair for all parties; but during a drought our White Plume became so destitute of sap that it took a great deal more in bulk to make a pound than it did of the Golden Dwarf and some other varieties. I also found that dipping it in water not only improved its appearance when it was a little inclined to wilt, but that the adhering water added much to its weight. In fact, we told a purchaser who had bought quite a lot, we would cheerfully wash it all for him for nothing if he preferred. He caught at the idea at once, and said he preferred the "unwashed." This same thing holds true of lettuce and a great many other things. I do not see any real substantial remedy except the golden rule.—I know there are occasionally a few berries in the fall, but those that I saw at Indianapolis were extremely large; in fact, they were larger than berries often seen on the market in regular strawberry time. Had it not been for their great size they would hardly have sold at 50 cents a quart, when fine peaches and other fruits could be had at moderate prices. One thing that struck me in their appearance was their light color. They were large, and of pretty fair shape, but very light colored for strawberries.

ARTIFICIAL PASTURAGE.

SCATTERING SEED BY THE WAYSIDE.

I WAS very deeply interested in the bee-pasturage question of Mrs. Chaddock's, especially alsike clover, in GLEANINGS for Oct. 15th, and I had decided to give my views upon the questions taken up in her article (not the latter part, of course). The question of bee-pasturage may be taken up in a practical and an impractical manner; and it is perhaps oftener the latter than the former. I will give my views, based largely upon practical experience and observation, and a little on theory.

It will not pay to cultivate plants for honey alone —that is, to take land fit for cultivation and sow or plant it with honey-producing plants which are of no other value. But if we can cultivate plants, etc., the flowers of which will produce honey, and at the same time you can secure from them an otherwise fairly remunerative crop, then you are all right. Or if you can scatter honey-plant seeds in places where they do not take up space which otherwise would be under cultivation, I consider such an investment remunerative. We should always, however, be very careful as to what we sow, that it be not a plant which will become a noxious weed. For instance, I could never permit myself to scatter one seed of "Viper's bugloss" (*Echium vulgare*); it is a pest in some parts of Ontario, where a few years ago it was almost unknown, and still a growing one, and no conscientious or right thinking man should scatter another seed of it until he finds out what its nature is. As to the Chapman honey-plant, I have seen it in bloom, have questioned closely Mr. Goldie, of Guelph, who had 50 plants on his grounds to experiment with, and who is an able botanist. Mr. Goldie stated that the plant is a biennial, does not increase from the root, is extremely hardy (*extremely hardy*, mark you), and, in his estimation, might easily prove to be a noxious weed. Now, are we justified in assisting to spread a plant broadcast over America which may prove to be another pest to those who cultivate the soil? If we assist and countenance actions which at least are a risk to our neighbors, have we a right to expect the fellowship and good feeling of such from a natural standpoint? No. We are a help and a profit to the horticulturist and agriculturist; do not let us run the risk of more than counterbalancing the benefit we confer.

Then we can profitably strive to have our neighbors, citizens, etc., plant such trees as we know are productive of honey. Much can be done in this direction, at a very small outlay. The linden, soft and hard maple, and, in places, willow, are excellent and beautiful shade-trees. And then we must be guarded in not overestimating the benefits derived from a flower. We stroll about after linden-bloom, and possibly near frost, and see bees working constantly upon sweet clover; are their frequent and continuous visits an indication of the quantity of honey obtained? By no means; it may simply be, and, I believe, frequently is, only an indication that there is *a little* honey there. There are no other honey-producing flowers about, and the bee, unlike some individuals when out of work, thinks half a loaf—yes, far less—is better than no loaf at all. Of course, a careful, observing, and experienced bee-keeper can readily see if such be the case or not.

Next, as to clover, and Mrs. Chaddock's argument, that alsike clover would not pay, as there is more honey in white than the bees can gather, I find that bees never touch the white after the alsike is in bloom. They commence blooming within a few days of one another. Bees will, in fact, leave white in the more immediate vicinity, and take alsike. As a honey-plant, my observations of five years prove to me that, during that time, it has not failed to secrete nectar which is slightly superior to the average white-clover honey. We all know white does fail. As to a remunerative hay and seed crop for the farm, it is decidedly that, and very much on the increase through our part and the most of Ontario. You, as a bee-keeper, can make no mistake by encouraging its cultivation, praising it, and giving away seed, to induce its cultivation. As a farmer, you can make no mistake if the soil is at all adapted to it—an inclination to a low soil, or, at least, not high, and not too light. As to buckwheat, it fails here at times. I do not think it would pay to cultivate it apart from its utility in plowing under for a crop of wheat. R. F. HOLTERMANN.

Brantford, Canada.

Friend H., there are extremes in both ways in this matter of troublesome weeds. Even buckwheat is an extremely troublesome weed if the seed is allowed to scatter itself; and it will come up year after year where a crop has been raised, and the seed allowed to shell. Friend Chapman is an experienced market-gardener, and knows all about weeds, about as well as any of us, and I think we can safely abide by his statements.

PERFORATED ZINC.

THE SIZE OF OUR PERFORATIONS JUST RIGHT; NO QUEEN CAN GET THROUGH.

I AM getting well started in the hive and queen-bee trade, and am doing better than I had reason to expect. My hive takes well, though some find fault with it. I am transferring and Italianizing every day. Your perforated zinc is exactly right. I would not have it changed a fraction. I believe it will hold the smallest queen, as I have daily trials of it in my swarming-box. I spend no time hunting queens. I rush all into the swarming-box, then draw the slide over the perforated side, and Bingham's "Doctor" soon empties the box of all except the queen and drones.

Some one said, in your journal, "Leave the old queen *in* till the new queen is ready to liberate." I tried it, at a loss of two queens—the first I ever lost in my life in introducing. Now I fall on the old way, and take out one when I put in the other.

Sealy, Texas, Oct. 19, 1886. J. L. DEWEY.

The results of your experiments with our make of zinc confirm exactly the results we arrived at as recorded on page 424, May 15th issue. We were very particular to have our machinist make the dies of just such a size as are the perforations of the zinc we send out. In the new edition of the A B C book now in preparation, we have carefully considered the proper size of perforation to be both drone and queen excluding, and yet permit the easy passage of workers. Your method of finding the queen by means of the zinc is good, and I should think it would answer an excellent purpose when it is desired to get a black queen out of a colony. We like the Peet process of introducing queens. By it we can take out one queen from a colony, and replace her by another at the same operation. The Peet process very rarely fails with us when the cage is properly fastened to the comb; and Neighbor H. says he can not remember that it *ever* failed with him.

PACKING BEES IN LONG BOXES FOR WINTER.

FEEDING, ETC.

MY father purchased a swarm of bees about five years ago, and three years later he gave me a swarm. We sell no bees, but keep them for their honey. We generally winter from 15 to 20. Some winters are unfavorable for bees—the winter of 1884, for example. Last winter we did not lose a single swarm. I will give you a brief description of the way I manage mine in winter. When cold weather sets in for earnest, I take the bees from their summer stands and place them in long boxes which will hold about five swarms each, placing the hives far enough apart in the boxes to pack dry straw and chaff around them, constructing a passage by means of two cleats nailed to a board, and placed at the mouth of the hive. This allows the bees to pass back and forth whenever the weather is suitable, and you think best. I always select a dry place, and have the boxes at least 30 inches from the ground. If it is where winter is severe, it is well to place a few cornstalks about them, as this protects them from piercing winds and frost. To make sure that they have enough honey, I lay two or three small sticks across the brood-frames, and place a card of honey upon them. This allows them to pass over the frames; and if they are short of honey they will have this card to fall back on. If there happen to be a bright sunshiny day during winter, it is well to let them take a fly; and then is a good time to see if they have honey enough to last them till spring. By the way, I generally change the cloth which is in the surplus-chamber, and give them a dry one, as the other will be frozen if there is any moisture to freeze. They are always damp or musty, and it is a good plan to give them an airing. If I don't have honey to feed them I make a thick syrup and turn it into some empty comb and place it over, just the same as I would the honey. When spring comes I place the hives back on their summer stands, and give them a clean bottom-board, as this saves the bees from carrying out the dead bees.

When it is time for them to begin hatching brood I give them some salt and water to work on, and also some stimulative substance, such as rye flour and oatmeal. I hardly ever make an artificial swarm. I always let them swarm naturally. If I want them to make honey instead of swarming, I look them over and kill all the queens but one; also give them more room to work in.

We use sections placed in a crate on top of the hive. This crate holds 24 1-lb. sections. A good strong swarm of bees will fill from two to three of these crates during the summer. Some do even better than that, but the average swarm fills about two.

ARTHUR W. JEWETT.

Mason, Mich.

KITES.

A LITTLE TALK TO THE JUVENILES.

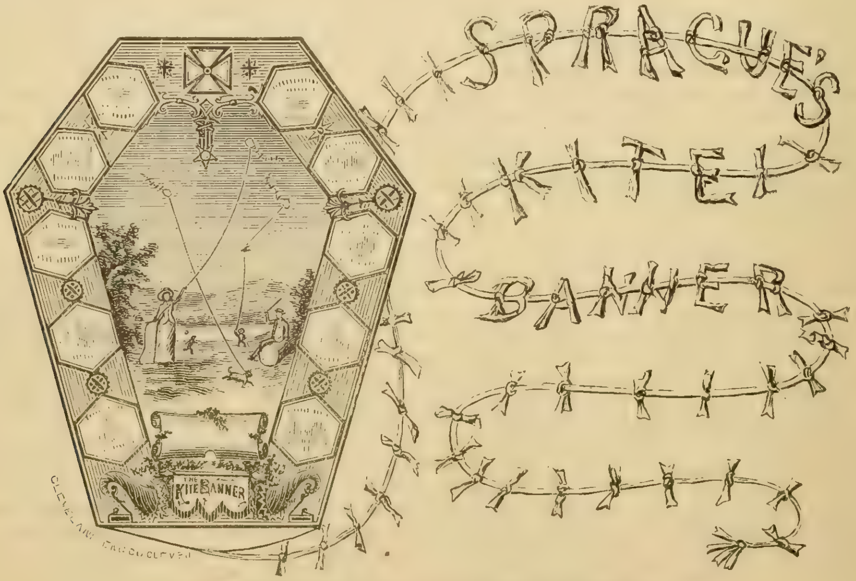
WHO has not enjoyed the sport of flying a kite? Did you never have a string broken, or have the kite come down in a tree-top, or across some building? Did you never get tired out in trying to make a kite fly, when there was not wind enough? and then some other day, don't you remember that the wind blew too hard and broke the string, or made the kite dive, in spite of various nondescript articles tied to its tail? Well, I have for many years wondered why somebody did not start to making kites by machinery—kites made of such carefully selected, light, strong, straight-grained wood that they would fly, almost without any wind. Sometimes I have threatened to start a kite-factory myself, but I never got around to it.

Only a few days ago some of the clerks said there was a man hunting for me, who had a patent kite. I found him, and we soon made a trade. They used to sell their patent kites for 25 cents; but when I spoke about buying a thousand, he got so excited about it he could not talk straight; but I bought the thousand kites, and paid him the money; and instead of selling them for 25 cents, I am going to sell them for an even *10 cents.* May be you would like to see what they are like. Well, over the leaf is a picture of the institution, tail and all.

This kite is made portable. The sticks that compose it can be folded up just as you would fold up a fan, and then they can be straightened out again. The paper is gummed around the edges, like an envelope, so all you have to do is to spread out the sticks, lick the edges of the paper, and paste it up, then hitch on the tail and string, according to the printed instructions, and there you are, all ready to fly it.

Yesterday there was a pretty good breeze, and so Huber and I started out to try one of the new kites. It shot right up out of my hands, and Huber just laughed and danced, and bubbled over with enjoyment while I let out the string, so it could go away up high. He said it was surely going to run against the clouds. But what do you think it did do? Why, I was getting ready to let him hold it, and was giving him a great amount of caution about not letting the string slip through his fingers; and to make doubly sure, I told him I would tie it around his waist. He said he would not let it go, but I thought I would not trust him. Now, then, what do you suppose papa did? Why, *he* let it slip through *his* fingers; and instead of running against the clouds, it just toppled over and sailed away over across the railroad track, and the string got tangled in an engine. Well, papa got the kite down from off the building, untangled the string and straightened it out, and spent more than ten cents' worth of time in getting every thing all right. But I thought it was better to teach Huber to take care of property, even if it did sometimes take more time than it was worth, than to teach him another lesson by going into the counter store and getting a new one. Well, we took the string over to

Uncle Hen's and let Aunt Mate and Gladdis Maud (she is the six-months-old baby that has come to live with Uncle Hen's folks) see the kite. Then we took it over and showed it to mamma, and sent messengers up on the string. The messenger was just a little piece of paper with a hole through it. The end of the string is put through the hole, and the wind spins the paper clear up to the kite. Then we tied the kite-string to Huber's cart, and, sure enough, off started the cart as if it were alive, and trundled away just about as fast as Huber could run, like a thing of life. When the wind veered around, the cart would run off to one side of the road, and run into the ditch, and upset; and then you should have heard him laugh and "holler" as he pulled it out. He got so excited with the fun he was having that I began to think he had better put the kite away until some other day, and then a team came along and was going to run over the string, and then he was in about as much trouble as a child often gets into. Why, he cried as if that kite-string were worth a hundred dollars, when a whole ball of it costs only five cents at the counter store. I wonder if older people don't sometimes make a greater fuss about the loss of a small amount of property. Well, before that naughty team had run against the kite and pulled it down, mamma came and showed him that, by going backward, he could raise the string out of their way. Is not this another lesson to poor shortsighted, worrying humanity? Mamma wound the string up on a piece of stick, and the kite came down careening and nodding, and cutting up all sorts of antics, as if it were a playful kitten instead of a few bits of inanimate wood and paper and string.



OUR TEN-CENT KITE FOR THE JUVENILES.

Now, whenever you want to make the kite draw a cart, remember to stop the cart whenever the kite seems to be getting too low. If that does not bring it up, pull your wagon backward until it comes up to a good height again. Now it will draw the wagon a good way before it gets down. If the wind is strong and steady, however, the kite will pull a cart or wagon at a pretty good speed, and not come down at all. The worst trouble about it is, if you want your wagon to run on a traveled road the changing of the wind will pull it from one side to another. Perhaps a steering apparatus, such as they have on traction-engines, might fix this all right.

While we were having our fun with it, a man stopped and inquired how long before I was going to have a kite hitched to our market-wagon, so as to dispense with horses.

Well, we can send you a kite, all complete, in a pasteboard tube, for just 10 cts.; and if you want it by mail you will need to send 5 cts. more for postage. We can send them by freight or express, with other goods, for 10 cts. And this reminds me, that three more numbers of GLEANINGS will finish the year 1886. As is customary, we will send it the remainder of the year free to all those who remit now for 1887. And as we don't want to show any favors to *new* subscribers that we do not to old ones, we will send a kite to every old subscriber who sends us $1.00 for GLEANINGS for 1887, before Dec. 1, always remembering that, if you want a kite by mail, you must be sure to include 5 cts. to pay the postage. If *new* subscribers want a kite, they can get it by sending us one more subscription instead of their own. We can furnish the kites at wholesale, 25 in a box, including one sample, all finished and trimmed, ready for flight, for 8 cts. each, or an even $2.00 for the whole, box and all.

REPORT FROM O. M. BLANTON.

From 425 to 475, and 31,000 Lbs. of Honey.

HIS OPINIONS ON SOME OF THE NEW DEVELOPMENTS.

THE honey season just closed has never, since I have been in the business, been more discouraging. My entire crop is unsold, and, with the prospect of having to put it on the market at 3 to 3½ cents per pound, leads me to wish I had never engaged in bee-keeping on a large scale. I shall try it one more year before I determine to abandon my favorite pursuit.

The season just past has been by no means the best. With a very wet cold spring which retarded the secretion of nectar, and, in addition, a severe drought in the month of May, extending into the middle of June, caused but a moderate yield. July and August were far better, and from late corn and cow-peas the bees recovered much of their lost ground.

I closed my apiaries on the 5th of September, determined to leave my bees an abundance of winter stores, knowing that, as it was of but little value to me, it would be of great benefit to them. I commenced the season with 425 colonies, spring count, and closed with 475. My yield was 60 barrels, or about 31,000 pounds, of extracted honey, and 600 pounds of comb. This is about as poor a yield as I have had since being engaged in bee-keeping. I must admit, that if I could have been able to give my personal supervision to my apiaries, the yield would have been greater; but circumstances beyond my control prevented.

I have read, in the different journals, many causes for the low price of honey. There are three, beyond a doubt: Overproduction, general depression of trade, and adulteration. The two first, in time, will rectify themselves; but the great evil in the last-named cause will always, in my opinion, be a bar to the prosperity of the bee-keeper. The low price of glucose, and the new discovery of saccharine, will stretch "imitation honey" to an indefinite extent.

I have been engaged in bee-keeping for fourteen years, and look back with surprise at the many trials and losses I have sustained in my experiments with varieties of hives and apparatus. How few I now use! The Langstroth hive (although not the only good one) I adopt, and most of them of 20 frames and one story. I find them more convenient and rapid of manipulation, which is of great consideration when working for extracted honey. I never use more than one inch in width of comb foundation as a guide for the bees on the top-bars of the Langstroth frames, or the one and two pound sections. I have abandoned full sheets of foundation with wire. Honey-boards, bee-feeders, queen and drone excluders, I find of no practical benefit. As for moth-traps, I am astonished that any sensible bee-keeper would use them. Reversible hives and frames, I will leave others to thoroughly test their value before I use them.

A wax-extractor I would not have; for with the old process of melting in boiling water, especially when two or three *pure* rain waters are used, there will be very few impurities left; and more so, if the fire is removed from the vessel containing the melted max and allowed to cool *extremely slow in the water* in which it is melted. The impurities should be scraped from the bottom of the cold wax before being melted again in another *pure* water. Many things that I have discarded may be of value to other bee-keepers in their localities.

As for packages, I find of value for me, for the home market, one and two pound sections of comb honey; and for extracted, one and two pound glass jars and one-gallon tin cans.

For shipment, I have, after many experiments, found that cypress barrels, fresh from the cooper, and made to order, containing from 525 to 550 pounds net, and with 16 hoops, are only to be relied on. These are my convictions, after so many years of experience.

I hope a silver lining may yet appear on the clouds now threatening our future prosperity, and that we may be encouraged to continue in one of the most agreeable and healthful occupations for the lover of country pursuits. O. M. BLANTON.

Greenville, Miss., Oct. 12, 1886.

Friend B., I am sorry to see you getting "blue" over the prospect. I supposed the low price of honey had about put an end to adulteration. You speak of honey being 3 to 3½ cts. per lb.; but glucose is quoted in New York at 4½. Now, they might adulterate the glucose with honey, but they could not adulterate the honey with glucose, at the above prices. If you sell your honey, even as low as 5 cts. per lb., is it not at this price going to compete with cane sugar? Friend Dadant said, at the convention, that he was not frightened at the prospect of only 5 cts. per lb. for his honey in quantities. It is, indeed, true, that where one numbers his colonies by the hundreds, he soon feels obliged to dispense with many of the fixtures which the bee-keeper of a dozen colonies thinks a necessity. We do not want you to desert our ranks yet a while.

BEES AND GRAPES.

A REMEDY SUGGESTED THAT IS AT LEAST SOMETIMES PRACTICABLE.

IN your editorial notes on page 798 you mention the wonder of visitors that the bees do not eat your grapes. I have about thirty bearing vines in my apiary, and visitors often ask me the same question: "How is it that the bees do not eat the grapes?"

Some even suppose that the grapes are raised for food for the bees. They are apt to look surprised, perhaps a little incredulous, when I tell them that I have never yet seen a bee eating a grape, though this is perfectly true. The reason for this is, no doubt, that there is almost always honey to be gathered here at the time when grapes are ripe. Bees care nothing for grape-juice when they can get honey. The chickens often eat our grapes, and bruise and mangle them so that the bees are not hindered from sucking the juice if they felt so inclined; but here they never have the inclination. No doubt, though, there are places where bees attack and at least partially destroy grapes that have been injured by birds or other insects, or that have cracked on the vines from overripeness or other causes.

It is superfluous to tell a person who has investigated the subject carefully, that bees can not injure sound fruit; but it is useless to deny that bees can and do injure grapes or other fruit, the outer skin of which has been broken in any way. Is it not best for us to meet this fact squarely and honestly? Should we meet damaging truth, or even mistaken prejudice and misrepresentation, with subterfuge and evasion? Is it not our wisest and safest course to recognize the fact that bees may and do cause pecuniary loss to fruit-raisers? Let us admit all that is true, and then do all we can to remedy the evil.

Your position in regard to screens for cider-mills is well known. A little trouble and expense will prevent a great deal of trouble, loss, and bad feeling. Let us see how far we can apply this principle to the protection of fruit from bees.

As I said before, the chickens eat my grapes. To prevent this I have been obliged to protect them in a way I am surprised never to have seen mentioned in the bee-journals. This plan is to place a paper sack over each bunch of grapes. Those to whom the plan is new, may laugh at it; but it is nothing new to grape-raisers. Many, who raise grapes by the ton, sack all of their grapes and find it profitable to do so. The advantages are, that the sacks protect the grapes from birds and insects, prevent mildew and rot, produce firmer bunches, which can be picked and handled without breaking off the grapes or destroying the bloom, and also protect the grapes from frost.

The method of using is to pin a one or two pound paper sack over each bunch, pinning the mouth closely around the stem with a cheap pin or wire nail. I have never seen the last recommended, but I find that a ¾-inch wire nail is just as good as a pin, and cheaper. The sacks used are the ordinary manilla sacks, and cost about 80 cents per 1000. Before using, the bottom should be perforated, else the sack will catch and hold water. Sacks are now manufactured expressly for this purpose, and may prove to be cheaper and better adapted. The best time to put sacks on is when the grapes are small, say the size of No. 6 shot. It can readily be seen, that if grape-raisers would sack their grapes a large part of the trouble connected with "bees *vs.* grapes" would be avoided. I think that, in a majority of cases, the vineyardist would readily adopt this plan if it were properly brought to his notice, and he could be induced to try it once. In some cases the bee-keeper could better afford to furnish the sacks free than to have his bees destroy his neighbors' grapes.

While we should always be ready to protect our rights when assailed, we should remember that others have rights too, and "as much as lieth in us, live peaceably with all men."

Perhaps this is a little out of season; but coming to him who has had trouble with his bees destroying fruit, it will be more apt to prove impressive than at the time for putting it in action.

Dayton, Ill., Oct. 12, 1886. J. A. GREEN.

Friend G., we are very much obliged indeed for the suggestions you give us. I was aware that many growers of choice grapes have been for some time in the habit of bagging them, but it did not occur to me before that it forms a perfect and complete remedy for the trouble between bee-keepers and grape-growers. The only difficulty is the expense, and trouble of putting on the bags. The way our grapes grow—tied to a stake, a good many of the bunches are so intertwined with the leaves and twigs it will be difficult to get a bag over them at all. Perhaps the usual system of training on horizontal wires would allow a bunch to hang down so as to make it much more feasible.

I should be very glad indeed to get the address of the manufacturers of bags for bagging grapes.—In regard to wire nails being cheaper than common pins, I think we have a kind of pins on our three-cent counter that is even cheaper than wire nails. There are, on a three-cent paper, 280 pins. I think this is a matter of very great moment indeed, and it behooves us to do all in our power toward encouraging grape-growers to use bags. I have found out this season that the baskets of grapes go quicker when the bunch is entire and the bloom on the grape is perfect; but I find it pretty difficult to pick grapes rapidly and not break and tear the berries. From what you say, I am quite satisfied we should make money to have our grapes all grown in bags, unless, indeed, we except a few bunches not worth bagging, or some that are twined in the branches so a bag will not easily go over them.

BALLING QUEENS.

WHY DO BEES BALL QUEENS THAT HAVE BEEN SUCCESSFULLY INTRODUCED?

On page 784, Oct. 1, 1886, Mr. John H. Mullin asks for information on the question of bees balling queens, and says it is not queens that are being introduced. Your answer applies only to queens which the bees have not accepted. You say, "Bees ball queens for the simple reason that they do not wish to accept them, and by that means they propose to sting or smother them to death." This answer fails to meet the question, as I understand it. His question refers to queens that are fully accepted—those that may have been bred in the colony (balling them) and laying for one or twelve months. In the past four years I have lost some of my most valuable breeding queens, just in the same way that he mentions—their own workers balling them, and in some instances stinging them to death. They do not always smother queens to death; for when very angry they often sting the queen to death. I have seen a bee, among the first to attack a queen, pop his sting into her abdomen under the segment band, and kill her almost instantly, after which they would ball her for a time.

Among the number of queens that I have lost in the way that Mr. Mullin states, were queens that had been bred and laying for one year and more; in some instances, in the same colony in which they were balled and *killed*. I have even had them killed the past season in three L. frame nuclei, after laying for 10 or 12 days, by simply opening the hive when honey was coming in very slowly. It is to this cause I have always attributed the balling of queens by their own bees. They are more apt to do it in early spring or midsummer, when a dearth of honey happens, if disturbed by being opened up and smoked, than they are in the fall. I have never had it occur with me in fall or winter, and I have repeatedly opened my colonies and taken out frames of bees when they were clustered, and could not fly off the combs. You do not do that up north, friend

Root, do you? The only remedy for the evil I have found is not to open hives except when bees are gathering honey; for in a honey dearth, any bees are likely to ball and kill their queens, if disturbed much at such times, unless in fall or winter, and then they are not apt to do it.

QUEENS REARED UNDER THE SWARMING IMPULSE —ARE THEY PREFERABLE?

Such is the heading of Mr. J. Eastburn's letter, page 786, Oct. 1, 1886. If I wanted more increase by *natural* swarming out, from queens which are not any more prolific than others which are not bred under the swarming impulse, I would take those that are bred under the swarming impulse; but for work, and best qualities combined, I always choose queens bred after the natural swarming impulse of bees has passed off. My experience has been, that the latter class of queens are fully as prolific, though less inclined to swarm, than those bred under the swarming impulse.

I have queens in my apiaries to-day that are three years old, and never offered to lead out, or swarm during that time. They were bred under the non-swarming impulse. If we desire bees that won't swarm, we must get them by breeding queens out of the swarming season, and contriving to select the most non-swarming of these to breed our drones and queens from. I will define, in part, what I consider the term "swarming impulse" implies; or, rather, the sense in which I apply it. That is the season of the year and the time when bees are swarming naturally, by Nature's own impulses, when they mostly all have the swarming fever inbred. Cells built at that time, and by such bees, are built under the *natural* "swarming impulse." Those built out of that season, either with or without stimulative feeding (to get them built perfectly, *well fed*, and as near the quality of those built under Nature's own impulse and desires), are built and bred on the non-swarming impulse. Queens from such cells as are built where stimulative feeding is followed, till cells are completed, out of swarming season, are such as I always select. But be it remembered, I have them built in full colonies and from freshly laid eggs. When honey is coming in plentifully from natural sources, stimulative feeding to get cells built is not desirable.

4—ABBOT L. SWINSON, 66—74.

Goldsboro, N. C., Oct. 14, 1886.

Thanks, friend S., for your correction. Since you speak of it, I see that the "footnote" does not cover the whole question asked by friend M. I have noticed that queens have been balled even after they have been in the hive for a year or so. Opening a hive during a dearth of honey, or just after a honey-flow, sometimes causes the bees to ball their queen, as you say. Bees are also apt to ball their queen a day or so after she has been successfully introduced, when a novice has a curiosity to look in and "see if she is all right." This is one reason why we use and prefer the Peet cage. It is so constructed that the queen can be liberated by the bees without the usual disturbance, noise, and jar. That is, every thing progresses naturally.

The balling of queens is sometimes caused by placing the hives too near together, or by having them too nearly of the same appearance. In that case, enough bees will get into the wrong colony to pitch into the queen because she is a strange one to them. I think a great many losses have occurred in this way because the hives were exactly alike, and closer to each other than they ought to have been.

FLORIDA.

GLEANINGS ADAPTED TO ALL LATITUDES.

IT was three years ago to-day that I came to Florida. I like it, its climate suits me, and will suit any person who adapts his desires to it. This is the secret of making any location agreeable to you—content yourself. You can not bring Ohio, Indiana, or Kansas here. If you so desire, you had better stay where you are. I you have no object in coming to Florida but to make money, please stay where you are, for that is the best place for you; for if you are making money, and that is your chief desire, you will be worth more to Florida where you are; but if your health is delicate, and of a pulmonary nature, there is little doubt but that you might be benefited by the change, unless you are greatly prostrated. In that case, die among your friends; but never—no, never, break up your home and move to any country until you have first seen it, considered all of its advantages and disadvantages pertaining to you and your avocation, and studied well all you expected to gain by the change. If you do not do this you will almost certainly be disappointed, and will be an injury to the country you may chance to drift into. All I shall say in praise of Florida is, that there is a great future in store for it. Those who come here and adapt themselves to the country and its climate, and direct their energies in unison with the facilities of the country, will do well here. The man who has done well before coming to Florida will usually do so here. "Nothing succeeds so well as success."

GLEANINGS AND ITS CONTENTS.

GLEANINGS has been with me for three years here, and seven years in Indiana. It was a good guide while in my Indiana home. Its teachings were closely watched; for then all the theories of the "wintering problem," "spring dwindling," chaff hives, cellars, clamp, packings, Hill's device, and a thousand other things that were then applicable to my profession as a bee-keeper, are of but little interest now, more than to see the different troubles that follow bee-keeping. We have our troubles here as well, but not as yet so great as you have. We meet with no loss from wintering, if we use any care. Birds, mosquito-hawks, and ants, are our worst enemies. Robbing must be guarded against; and, as Ernest says, you must see to it yourself, for there is no great excellence without great labor.

The scientific and working principles of bee-keeping, as taught by the different authorities, are applicable to us in Florida as well as with you. This makes GLEANINGS very dear to us here. The Heads of Grain are closely winnowed, and much good seed has been garnered. The Tobacco Column has been chewed and smoked by the lovers of the weed, and many "smokers" changed hands.

The Reports Encouraging and Discouraging show the ups and downs of life as returned by the different members of your family of bee-keepers. Those discouraged, they bid "Hold the fort;" and those who rejoice in their prosperity, they bid be charitable, and give as it is given unto you. "Notes and Queries," and your replies, have been closely scrutinized. Humbugs and Swindles have been exposed, and no reader of GLEANINGS need lose by them. Our Own Apiary has been closely watched, and from its management have been gathered many lessons of profit. "What to Do, and How to be Happy While Doing It," gives us in Florida more interesting reading than "How to Winter Our Bees" does. How to grow good vegetables is now to us a question of very great importance; for on that, to a great measure, depends the prosperity of Florida. Myself and My Neighbors—we are all neighbors, and I did hope that I could meet them at the convention this week in my native State, at Indianapolis, but I can not. This brings me to Our Homes. "God Bless Our Homes!" should be over every man's door, and should be engraved on every man's heart; but, alas! the "Blasted Hopes" that are in many blasted homes, caused by intemperance. May God so open the eyes of every praying Christian in this land, so that he may see to vote as he prays, that the *cause* of the curse may be removed from our land. "Woe unto them that are mighty to drink wine, and men of strength to mingle strong drink; which justify the wicked for a reward, and take away the righteousness of the righteous from him."—ISA. 5: 22, 23. JOHN CRAYCRAFT.

Altoona, Orange Co., Florida.

I am sure, friend C., we are very much obliged to you for your kind and encouraging words; and we can say amen most heartily to your closing text.

UPWARD HIVE VENTILATION.

CAN BEES WINTER IN HIVES ABSOLUTELY TIGHT ABOVE? ETC.

ALTHOUGH it has been stated so, yet I should be glad to know to a certainty whether a colony ever passed a confinement of 90 days on natural stores, and without a particle of upward ventilation to the hive, and came out undiseased. Less than a week ago I chanced to meet one of those cranks who always cling to nature's methods, and winters his bees with (supposed to be) tightly sealed brood-chambers. He said his method was the correct one, and that his success attested the truth. I began to feel elated at the prospects of learning something of this vexatious method of wintering. But, lo! it was found that his hives *did* have real upward ventilation, as, when they were inverted, water went out of them faster than it could be put in with a pint cup. Then and there his cherished old-fogy notion was shaken. It needs only a small amount of ventilation for a colony of bees. About such a circulation as would pass through 2 inches of loose chaff is sufficient in a temperature of 45°. If the temperature is above that point there should be less chaff, and a lower temperature would necessitate more chaff. A very few open cracks in a hive would provide that amount of ventilation, which would be likely to be a sufficiency. It seems to many, that a cluster of bees causes considerable warmth and circulation; but the fact is, in the case of a well-wintered colony, that there is as little draft as possible, and yet be worthy of the name of a draft.

One would be led to believe that a ½-inch hole above the cluster would admit sufficient draft to carry off the overplus of moisture. The amount of moisture generated by a cluster of bees is inconsiderable, with the outside temperature at 45°, as the average temperature at the center of a cluster is about 70°, which decreases until an inch outside of the cluster finds it at 55°. So little difference in temperature could not produce much circulation; and without circulation, moisture will not accumulate. Still, a certainty remains that there is and must be some draft which must condense its moisture either inside or outside of the hive. Many apiarists know, and all observing ones ought to know, that when a colony clusters in the top of the hives the lower parts of the combs become covered with mold or moisture. Sometimes the moisture is of sufficient quantity to run out at the entrance. This moisture never would have accumulated there had there not been gusts of air warmer than the outside air forced in that direction.

There is, it appears, a small amount of warm air thrown off from a cluster of hibernating bees. This warm air, if it can not proceed upward, will go downward. A comparatively large share of it penetrates the solid board composing the side and cover of the hive, but still there is room left for disposal. What we need to provide is an arrangement of the hive that shall allow the upward movement of this surplus warm air. I call it surplus, as that is what I consider all drafts that proceed in a downward course in the brood-chamber, and do not pour out at the entrance. I feel safe to say, that not one colony in 100, when they are in the quiet state, will produce enough heat to fill an ordinary hive and pour out at the entrance; so if I am right we might as well give up ventilation at the bottom of the hive. All the advantage there is in leaving the bottom-board off the hive is to let out the foul air (which always sinks), and thereby prevent molding of the combs; but mold does not hurt bees, as they never consume it or attempt to move it until a flight. What is needed is an amount of ventilation at the top of the hive that will cause all drafts of the hive to move in an upward direction. Then there will be a constant movement upward through the brood-chamber; and if condensation takes place it will be above the cluster; and if the cluster is situated just below some loose chaff or forest leaves, the moisture will be out of the reach of the bees. It is not the results of cold air coming in contact with warm air that condense moisture, but the coming of the warm air in contact with the cold. When cold air comes in at the bottom of the hive, and condensation does not take place until it goes out at the top, if the outside air is not already saturated its tendency would be to absorb rather than discharge moisture.

Some may be of the opinion, that the circulation about the cluster would continually force the condensed moisture beyond the reach of the bees. This is partly the case. The heat and circulation of the cluster of bees do render the combs dry for some distance around the cluster; but, as I intimated before, there is not enough of this circulation of air, nor the force to drive it to all parts of the brood-chamber; and a part, and often it is a very large part, of the combs that is occupied by moisture, sometimes extending up at the side of the cluster to the top-bars. Now, the presence of this moisture is nothing detrimental; but as time and days roll on, some of it, getting into honey-cells, ferments. In fact, I do not know but there is some other ingredient drawn in, or the pollen exerts some wonderful power, as it hardly seems possible for a mixture of honey and water to form so sour and sticky a mess as is often found.

From this foul accumulation proceeds an acrid fume which (unlike the gas spoken of before) rises to the top of the brood-chamber and there continues to accumulate, making the bees uneasy, and they begin to move about; some of them attempt to move the moisture, others sip sour honey; but generally the bees exercise violently, and consequently die of early old age. The last of the bees in the colony, finding it a hard matter to keep warm, are forced to activity, and the consumption of honey, which, taken on to a cold and disordered stomach, passes into the intestines and forms the watery and half-digested liquid that causes the distension of the bees, and soiling of the surroundings, in case of true bee-diarrhea.

Those who winter their bees with tightly sealed brood-chambers are often heard to complain that their bees got restless and uneasy from being too warm. My experience has verified that it is not the *warmth*, but it is the *fume* of the sour and fermenting mass below, rising and accumulating in the upper portions of the brood-chamber; and the removal of the solid cover at such a time would convince any person of the truth of my statement. C. W. DAYTON.

Bradford, Iowa.

PIPING OF QUEENS.

ALSO, CAN A QUEEN FLY AS SOON AS HATCHED?

I WAS very much astonished at Mr. E. S. Miner's article, found on page 778, Oct. No., and at friend Root's "supposing" the piping noise of queens is made with their wings. Why I was astonished at Bro. Miner, was that I have watched scores of queens in the act of piping, and never yet saw one move her wings further than a little tremulous motion produced by the tremor of the body. I am no scientist, but believe the noise comes from the inside of the thorax, from all the observations I have taken. Why I have watched this matter thus closely, was because Quinby, in his "Mysteries of Bee-Keeping Explained," attributes the noise to the queen's wings. In nearly every thing Quinby wrote in said book I found him unusually correct; so when I heard, for the first time, that a queen was piping on a frame I held in my hand, of course I expected to see her go through an operation as described by Bro. Miner. Instead of this she merely drew her body down a little closer to the comb and uttered the note, without moving, save the tremulous motion spoken of above. Since then I have watched scores, as I said before, only to see the same thing. However, I might not be so positive regarding the matter, that the wings are no help in making the noise, were it not that I have often heard old queens pipe when they had their wings clipped. As I keep all of my queens' wings clipped, it often happens, during a rush of swarming, that many of my swarms are allowed to return back where they came from, to wait until another day, when I can attend to them. In such cases, old queens will, quite frequently, pipe.

A year or two ago I had a swarm kept back by rainy weather till the young queens were about hatching, when it came out. For some reason which I do not now remember, they were returned, and the next morning I went to cut out the queen-cells to save them, when I heard the old queen piping loudly—in fact, the loudest I ever heard a queen. This queen I know had only very short stubs of wings, as I often clip every bit of all four of the wings off which I can get off, so I was again curious regarding the matter, and watched her for several minutes. The performance was the same as with the others, so the matter was for ever settled, in my mind, that the noise in piping is not made with the wings.

Now, I would not say a word regarding the so-called "nonsense" of queens piping in the cells were it not that I wish to correct what I consider another mistake, which is, that some assert that a queen just matured can fly. Perhaps there is no one point in bee-keeping that I have given so careful attention to as this. What I mean by a queen just matured, is, such a one as leaves the cell at the time she is ready to come out, or mature; such as hatch first in a colony, or such as are hatched in a lamp-nursery. All such queens can not fly, any more than can a worker just hatched, nor peep either, and do not do so under 12 hours from the time of hatching. My observations say a queen must be 12 or more hours old to either peep or fly, and she can fly as soon as she can peep, whether she is in the cell at this time or not. I am not surer of any thing in bee-keeping than I am that queens peep in the cell, for I have had them do so while I had my ear to the cell listening. Let me explain a little:

Three queen-cells on one comb are sealed at the same time; and if nature has its course, all will mature in seven days, during warm July weather. If the bees do not wish to swarm, all three will be allowed to come out of the cells at once, when soon all but one will be killed, none of which can fly previous to killing. If the colony is an extremely strong one they may run about unharmed for an indefinite period, *a la* Jones, and might stay long enough so some might fly. If other cells not so near maturity are in the hive they will be destroyed, so that no piping will be heard.

Now, we will take the same three cells again, but this time the colony desires to swarm. One of the three is allowed to hatch while the other two are prevented from leaving the cell by the bees clustering about them. These queens mature the same, and are just as old as is the one which is roaming over the combs. They cut the capping of the cell the same as did the other, but the bees put wax over the joint all around, except a little spot from 1-32 to 1-16 of an inch long, through which the queen puts her tongue, to be fed by the bees, which they do as often as food is required. Not far from 20 to 24 hours elapse, when the queen that is out is old enough to think of leading out the swarm, so she begins piping, which she continues to do 20 to 30 hours longer, when, if the weather is good, the swarm issues with this queen, she going out with the very first bees of the swarm. The other two queens are just as old as the one gone out, and have been piping in their cells nearly as long as the other piped outside. They are also ready to fly as soon as the bees or the apiarist lets them out, and often get out with the latter end of the swarm, so we frequently find from two to 20 queens with after-swarms. These queens have been matured two days, even if they are seen just hatching, and, in my opinion, no queen of any race, Syrian or any other, can fly when first hatched, unless she has been kept back by the bees. G. M. Doolittle.

Borodino, N. Y., Oct., 1886.

I too, friend D., have often watched queens while they were uttering their piping note; but from the movement of the body, I always supposed the wings had something to do with it; although I did not and do not now think the note was caused by rubbing the visible portions of the wings together. In fact, I do not know much about it? Will Prof. Cook or Prof. McLain tell us something about it? I have seen queens take wing within a few minutes from emerging from the cell; but very likely they were by some means, or for some reason or other, kept in the cell until they were several hours or perhaps a day old. No doubt you are right about it.

HOW TO MAKE LABELS STICK TO THE CANS.

A RECIPE FOR HONEY-CAKES.

I SHOULD like to tell some of the many readers of Gleanings how to put labels on tin cans, and have them stick so they will not come off. Make a thin solution of white glue, then thicken it with wheat flour until it is about the consistency of paste. This is to be made the same as any other paste. Cover one side of the label with the paste, then put on the honey can or pail, and I think you will not have any trouble about the labels coming off. I would suggest that there be something more printed on the labels, perhaps some recipe for cake or pies. Of course, they are to be made with honey, or, at least, part honey. We ought to think of some way to help sell more honey, and I think this way we have spoken of may help the bee-keepers to sell more honey, provided the honey is pure and nice.

I will send you a recipe for cake. It is nice to have it warm for tea, or equally good when cold. One-half cup of honey; one-half cup of sugar; one-half cup of butter; one egg; two cups of flour; one cup of cold water; two teaspoonfuls of baking powder. Flavor with lemon or vanilla. This recipe will make one large loaf, or can be baked in gem-pans. Mrs. Jennie M. Johnson.

Rexford Flats, N. Y., Oct. 9, 1886

NORTH - AMERICAN BEE - KEEPERS' SOCIETY AT INDIANAPOLIS.

Handling and Caring for Liquid Honey.

SOME VALUABLE FACTS ELICITED FROM FRIEND MUTH AT THE INDIANAPOLIS CONVENTION.

THE following facts were brought out by a series of persistent questionings, and I presume friend Muth was waked up to give them with a little more earnestness because one or two in the convention seemed to think they knew more about it than he did. Please bear in mind, friends, that Mr. Muth has probably handled more liquid honey than any other man on the face of the earth. He has had experience with it by the hundreds of barrels, and has kept it for years, and finally disposed of it all, I presume, at a paying figure. Friend M. is by no means a man who does business without pay.

Perhaps many of the friends remember the position he has always taken, that honey need not be left to ripen in the combs, but that it will ripen itself, if left exposed to the air, in almost any kind of open vessel. Some of us have been pretty much decided against this; but when the matter was fully explained at the convention, I began to feel ashamed of myself that I had not perceived it before. For instance, if we have a quantity of extracted honey in an open vessel, the heaviest portion will soon sink to the bottom, and the thin honey will be found on the surface. Now, if I should dip a saucerful from the surface of a barrel of honey in this condition, and it should taste raw, thin, or even a little as though it were fermenting, I should be inclined to call the honey bad. Not so, however, says friend Muth. Put it where the air has free access; cover it with wire cloth or mosquito-netting, or any thing that will keep out insects and yet permit evaporation, and in due time it will come all right of itself; that is, when the surface has evaporated to the proper thickness, the taste of the honey will be much improved, and the bad flavor gone. Dr. Miller stated that he had taken honey which he supposed was sour, or spoiled; but he found that, when placed in a shallow vessel on the reservoir of the stove, it would, in the course of time, become thick, sweet, and good. Sometimes honey is gathered and barreled when so raw and unripened that it will expand so as to bulge the heads of the barrels. If you bore an auger-hole in to relieve the pressure, the honey will fly out and shoot against the ceiling overhead. A novice might say that this honey had fermented, and was all spoiled. Not so. Give it free vent; expose a considerable surface in open vessels—crocks, pails, barrels, large tin cans, or whatever you may choose, and it will in time evaporate out all the watery part that rises to the surface, and become thick, nice, ripe honey. I presume, of course, these receptacles should be placed in a dry room, for a cellar might be so damp as to cause moisture to collect on the surface. Housewives frequently scald preserves to make them sweet, and succeed perfectly, even after there is quite a perceptible taste of fermentation. Now, the process of curing unripened honey is precisely the same, only it is done at ordinary temperatures. The result accomplished is the same—getting rid of the surplus moisture. If you spill some honey, and let it remain several days, you may notice it gets thick, and finally becomes like wax or gum. It slowly parts with a portion of its water. Honey in an open vessel will do the same thing, if you give it plenty of time. The warmer and drier the room, I presume, the better. Friend Doolittle does the same thing with comb honey, to evaporate and thicken the honey in the unsealed cells; and he does this, as you may remember, in what he calls a honey-room; namely, a room with plenty of windows, so that the sun may raise the temperature to a high degree.

My friends, if you want evaporation to go on rapidly you must also have a strong current of air through the room. A few days ago I undertook to dry some green corn placed on shallow pans in the greenhouse. It got very hot indeed, but it just soured very promptly without getting dry a bit. The same pans, placed in the open air in the sun, dried the corn at once, without any souring at all. In the latter case the air was constantly changing above the corn. In the greenhouse it was, to some extent, close or confined. We did not have ventilators enough to get a constant change in the air above the corn, as it gets when it is out in the wind as well as in the sun.

The following letter, bearing on this matter, is just at hand :

> I shipped 5 iron - jacket 10 - gallon cans, with extracted honey, weighing 115 pounds each, last October or November, to Messrs. ——— ——, and to-day I received the inclosed account. Please read account, letter, etc., and review circumstances. It seems to me proper for you to advertise such merchants as frauds, and protect the apiarist from losing his hard-earned products. CHAS. DORFMAN.
>
> Pittsburg, Texas, Oct. 5, 1886.

The commission men returned 2½ cts. per lb. for the above honey, saying that it so soured they were obliged to get rid of it for what it would bring. After paying the freight and all other expenses, friend D. received less than one dollar for five iron-jacket ten-gallon cans full of honey. Now, it is quite probable, that, had the commission men understood the matter referred to above, the honey could all have been restored to a good article with a very little trouble.

QUEENS FOR HONEY, INSTEAD OF QUEENS FOR YELLOW BANDS.

Dr. Miller remarked that he had two colonies of Italian bees that gathered white honey, resembling clover in taste, at the same time that all the rest of the apiary was gathering dark honey from buckwheat. Others have probably had a similar experience. The honey was probably gathered from red clover, as this is in bloom at the same time with buckwheat. Well, Dr. Miller asked the question, if it were not likely that he could get a strain of bees that would gather clover honey in the fall by raising queens from these two colonies. I presume that all present at the convention had no doubt but this trait could be encouraged and fixed in a few generations; but Prof. McLain remarked that we want to raise *drones* from these desirable colonies — not *queens ;* for it is a recognized fact in producing new strains, that the male could have by far the greater influence. For instance, as an experiment I have been raising chicks from some of my small hens that were extra good producers. One of these hens was a Brown Leghorn, and a pretty dark-colored one at that. She was crossed with a Light Brahma, and the greater part of her chicks closely resembled the male bird, although in size and movement they much resembled the little dark mother. I made a similar cross with Langshans, and these chicks, too, resembled the male bird so much that they were very fair Light Brahmas.

Again, my cousin, D. E. Fenn, of Tallmadge, O., is an importer of hornless cattle. As a matter of course, he talks eloquently in regard to the advantage of cattle without horns. The fact that they have no dangerous weapon, ready to use at a moment's notice, removes temptation, and therefore they are of mild and gentle disposition, etc. These cattle were imported from across the ocean, and the males are, many of them, worth a great pile of money. People ask how they are to get their money back on such an expensive investment. Now, here is the point : Cousin Fenn has experimented largely in crossing common stock, with the view of shortening or getting rid of their horns ; and, strange to tell, where the male parent is of this hornless breed, no matter what the female may be, the progeny have lost their horns ; but where the male has horns, and the female none, the progeny hold on to the horns. So you see that Prof. McLain may be right in scolding because we talk continually about getting queens for new blood, and say so little about the drones. Now, then : When you pay a good deal of money for an imported queen, or a choice home-bred queen, if you please, go right at it at once and prevent drone-rearing in all your other stocks, but encourage an abundance of drones from your imported, or choice queen, in every way in your power ; that is, make this queen furnish drones enough to meet all the young queens you raise, or that may be raised without your knowledge.

WIRE CLOTH FOR SEPARATORS.

Friend Betsinger, who was one of the first to use tin separators as we now use them, has been experimenting a good many years on different materials for separators. He has settled down upon galvanized wire cloth with meshes large enough to let the worker-bees pass through. Of course, a greater space is required between the combs of capped honey where even a wire-cloth separator is used ; but he thinks, aside from that, the bees go to work in sections just as well as if no separators were used at all. He says the bees build no bridge-combs against this wire cloth. As nearly as I can judge by the looks of the wire cloth, it is the same thing we advertise and sell for fish-ponds, four meshes to the inch.

THE PROPER SPACING OF FRAMES, A LA POND.

THE RESULTS AS TRIED BY A SCHOOLMASTER.

THE editorial comments on Mr. J. E. Pond's article in GLEANINGS of Oct. 1, p. 779, open for discussion a question of great interest to every bee-keeper who is working for comb honey. I can not agree with friend Pond's statement, that " the production of brood is in our own hands," through the proper spacing of frames. In my experiments during the past summer, with hives constructed on the Heddon plan, I noticed that sealed honey and sealed brood occupied cells of a uniform depth. These combs were built on full sheets of foundation; and when honey and brood were sealed, the surfaces were "as flat as a board." But that fact did not deter the bees from filling the outer frames with honey early in the season, nor from occupying a narrow strip of the upper part of every brood-frame with stores. As soon as the bees began work in the sections I uncapped these stores in the brood-nest, and the two sections of the brood-chamber were inverted and interchanged. According to the theory of close spacing, this honey should have gone into the supers, but it didn't. Those contrary bees quietly gathered it off the bottom-board and put it back into the very cells it came out of, even replacing it below the brood. This is at variance, too, with the reversing theory; and since my experiments through two summers have invariably led to the same results I am forced to believe that neither of these plans of management will give us absolute control of the production of brood. Although we may succeed partially in overcoming that instinct of the bees that prompts them to surround their young with an abundance of food, we can not wholly control it.

Quite a number of the hives in my apiary are 14⅛ inches square inside, and hold frames ten inches deep. In some of these hives there are ten frames; in others nine. At no time in the season can I detect any difference in the brood area of a frame from a hive of ten frames, as compared with one from a hive of nine. The proportion is the same in both. But, of course, the ten-frame hive will have the advantage in the total area of brood, and only in that respect will it meet the conditions of Mr. Pond's theory. From these facts it will be seen that nine combs, closely spaced, will give no more brood than nine frames further apart; but there is one thing very evident: With combs wide apart, the bees will loaf in the brood-chamber all summer. This I have proven to my sorrow; but when the frames are crowded close together in the honey season, the bees use no ceremony in entering the supers. For placing this plan so plainly before beekeepers, friend Pond is entitled to the thanks of the entire fraternity. **Z. T. Hawk.**

Denison, Iowa, Oct. 12, 1886.

Friend H., your experience is just about the same as ours has been; and I always had an opinion that loafing-room anywhere inside of the hive was a bad thing.—I emphatically favor crowding the bees up into the sections, or outside; that is, when honey is to be had in the fields plentifully.

CASE FOR SECTION AND SEPARATOR COMBINED.

SOMETHING THAT HAS AT LEAST THE CLAIM OF NOVELTY.

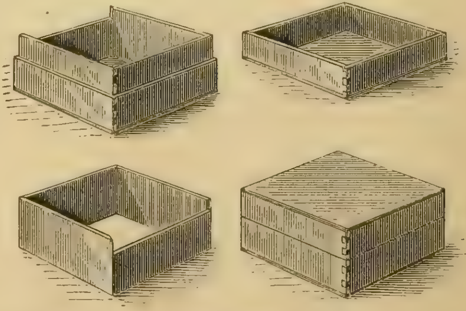
I WILL send you by mail one of our section boxes. We should like to have your opinion on it. You will see, on taking it apart, that it is in three pieces. The inside is like a common section, except that the bee-space is all on one side, and only on the bottom. The other two parts are covers to slip on over the shell. One is a little wider than the other,

To use the box, the narrowest cover is taken off and put away. Then they are a section closed on the back, and they can be entered only at the bottom, when they are on the hive; when they are on the hive, the back of one row, it will be seen, answers as separators to the row behind it. When they are to be removed from the hive, lift them out of the case and remove the shell from its cover, and turn it over and replace it so that the part that the bees have not soiled with propolis comes on the front; put on the other cover that was laid away, and it is done.

I think I can see two objections that will be put down at the end of this. One is, that the bees will not enter them readily. We have given them a pretty fair trial this year with blacks, Italians, Syrians, and a strain called the Bellinzona strain of Italians (but we think they are Cyprians), and we have put open and closed boxes on the same hive, and we could see no difference in the way the bees entered them; and in some cases the closed boxes were filled first. The cost is $15.00 a thousand, or 1½ cents each. Now you will say they cost too much. Let me give you a few figures. Common sections cost about $5.00 per 1000. Separators cost $1.50 per 100. It will take about 200 if they are used with the Root cases, which will amount to $3.00. The cost of pasteboard boxes to hold sections of honey is $9.00 per 1000. Add this up and you will have $17.00. Our box answers the purpose of all three; besides, they come all put together. Besides that, honey in old-style sections sells at 20 cents, and honey in these boxes sells readily at 22 cents. This more than pays for the difference in the cost of the box. We get double Mrs. Chaddock's prices here for honey—20 cents per crate; 25 cents per box, open boxes. **Ralph E. Gould.**

Lisbon, Me., Sept. 26, 1886.

We can better explain to our readers the above invention by means of the cuts shown below. The whole thing is the well-known Hutchins' patent, dated 1874; but the box is made for a packing-box, and not for a honey-box at all. Many of our old readers will remember that it has been several times mentioned before. It is made exactly as our one-piece sections are made, folded by a V-shaped groove, dovetailed at the corners.



GOULD'S ARRANGEMENT FOR COMBINING A SECTION CASE AND SEPARATOR.

The lower figure on the right-hand side represents the packing-box as made by Hutchins since 1874. The two upper figures show the same with the cover removed. Now, the only change needed to make it ready to go on the hives is to cut out a portion of one side as represented in the cut, so as to make an entrance for the bees. The covers, which are a little shallower than the bottom, are to be laid away when the sections are placed on the hives. The other parts are simply placed on the hive close together, with the openings downward. They can be put on to any of the common cases in use, so as to handle them all together if you choose. Of course, a strip of foundation, or enough to fill the whole section, is to be put in to make the bees build their combs straight. When the sections are ready to come off the hives, slip on the covers that were laid away, and they are ready for shipment. When you wish to exhibit them to customers, slip off the *bottom* of the box instead of the top, and you have exposed to view that portion of the section that has never been exposed to the labors of the bees at all. It is as bright and clean as when it left the buzz-saw, for it has always been boxed up until this very moment. It is true, the bottom part of the box has been exposed to the travel of the bees, and may be somewhat gummed; but the ordinary lithographic labels, such as are used on our pasteboard boxes, will cover this bottom completely; and when they are placed on the shelves or counters in the grocery, the bottom can be viewed instead of the top of the box. The top of the box will be nice and clean, of course, for it was never exposed to the bees at all; in fact, these covers should be shut up in a dark box, to keep the sun from fading the fresh color of the wood.

Now, then, the thought comes up, this is all very well in theory, but who has ever tried it to know whether it will work or not? Well, here is what friend Gould reports :

We have run our bees entirely for comb honey. We started this spring with 18 swarms; we have now 34 swarms, and have taken about 1400 pounds of honey. The clover season was good, but I don't think we got a drop of basswood honey this year. We have had in the same yard this year, blacks, Syrians, Italians, and the Bellinzona strain; but the blacks have surpassed them all. The Bellinzona did nearly as well as the blacks, but they are so ugly it is more than it is worth to handle them. One swarm of blacks gave us 4 good swarms and 25 pounds of honey. The Syrians don't get ready to work till clover is all gone, and then there is nothing to do, and they take to robbing. I believe they had rather rob weak swarms than to get honey honestly. The fall flowers have been very good here.

RALPH E. GOULD.

Now, dear friends, you know all about it I do; but the arrangement is so exceedingly ingenious that I have decided to give friend G. this free advertisement. The price, too, for a section with a case to put it in is very reasonable. The only difficulty I see is the extreme accuracy of the workmanship required to have them fit exactly; and I am afraid there will have to be some scraping done when the boxes are taken from the hives, so as to allow the covers to go on. The sample sent us is also a little frail, and I should be afraid the moisture of the hive might cause the glue, used in putting the boxes together, to let go its hold. Friend Hutchins, however, is a large manufacturer, or, at least, I have been told so; and as he has been many years in the business, he probably knows how to make and use materials that will stand even dampness.

THE WEBSTER FUMIGATOR.

SOMETHING FROM THE INVENTOR.

I MUST thank you very much for your evidently unbiased expression of opinion on my fumigator; but I must "pick you to pieces" a little over the matter, and endeavor to set you right on one or two items. You take exception, in no small degree, to its smell, and also to its making your hands dirty, with what you call the "sticky" matter. All these effects are due to one cause; namely, improperly filling the sponge. Now, there is no "sticky" matter whatever used in the "agent," so that nothing sticky can possibly come from it; but the sponge, being improperly filled, the "agent" is blown on to the varnish of the bellows; and the varnish, being partially dissolved by the carbolic acid, so becomes sticky. Just try this: Pour a little of the agent on your hands. It will wash off directly with soap, and I know you can't feel any stickiness in it. If the sponge was properly filled, this would not happen; and, no portion of the agent having escaped, your clothes could not possibly smell of it.

Of course, there is a right and a wrong way of charging a smoker, and there is also a right and a wrong way of charging a fumigator. You'll say, "You ought to have told me this before." So I ought; but then, we are not exactly next-door neighbors.

I always, after charging the sponge, take a piece of old rag and squeeze the sponge in it, not removing it from the hooks; the rag prevents the acid getting on your hands, and takes up the surplus that escapes; after which there is no chance of any of the agent being forced out at the cap on your hands, clothes, or bellows.

I do not know whether the American bees are less amenable to the fumes of carbolic acid; but here in England I can handle them better with such than with smoke. On first using the fumigator one feels that it can't be of much use, the same as you did before trying it, as nothing is seen coming from it; whereas bee-keepers have been used to seeing volumes of smoke issuing from the smoker. During three weeks I examined over 200 stocks, and on no single occasion used smoke; in fact, I never use any, and am handling bees every day during the season. Now, you mustn't take the above as a "puff" on my invention, as, in America, such is of no use to me in England, in a monetary sense I mean, you being able to make and sell them as cheap, without sending here for them. My object is simply to lay before bee-keepers an appliance that will economize labor, and help to make the pursuit of bee-keeping more pleasant to its votaries. We are all aware that the smoker is one of the most unsatisfactory tools we have to use.

Wokingham, Berks Co., Eng. W. B. WEBSTER.

Thanks, friend W. Although you are not strictly a "near neighbor," yet even if the Atlantic does intervene, I feel as if I could reach your hand just the same. After pouring a little of the agent upon my fingers, as you directed, I find that it is not sticky. Your supposition, that I got a little of the liquid upon the varnish of the smoker bellows, is correct; and hence, not recognizing that the varnish was the real factor that caused the stickiness, I reported that the agent was "sticky." But as regards the odor, I beg to take issue with you; and further trial with the agent confirms my first statement. I have no doubt but that you can handle 200 colonies successfully with the fumigator, and I believe I could do it here with only gentle bees; but with smoke I think I could examine the same number not only with more safety, but a half quicker. I speak whereof I know, for I have handled fifty colonies with your fumigator.

ERNEST.

THE TOAD, AND BEE-STINGS.

ALSO SOMETHING ABOUT KING-BIRDS CAPTURING BEES.

WHO has not heard many things against the toad? When a mere lad I was told that, should we touch but the skin of this old honest-looking acrobat, warts would cover the place that touched the cold clammy cuticle of his toadship. Strange it is, how such opinions gain currency. It is said, that misery loves company. I never quite believed it; but if it is ever true, we might think that our warty amphibian might like to sow a full crop of warts on whatever he saw or touched; but I early learned that, had he the wish, he has no power to bequeath his excresences to aught except his own kith and kin. I always loved honesty, and there is a frankness and honesty in the look of the toad that captivated even my childhood's eye. So, per force, I had to shake hands, gain the acquaintance of, and make friends with, this honest, warty old toad. As a result, I received, not a wart, but a very companionable friend. Thus it was that I learned his many good traits.

Few of the animal kind are better insect-hunters than the toad. He delights to roll them, not as a sweet morsel *under* his tongue, but as a savory mouthful captured *by* his tongue. It is just fun to see a toad gobble down a fly, ant, or beetle. This is how he does it: The fly stands off some distance, winking in fancied security, when, all at once, the great jaws of his toadship open wide, and the fly darts into the cavernous mouth as though it were home, and he were sent for. Closer scrutiny shows that the long sticky tongue of the toad just runs out with a rush and "runs in" the unsuspecting fly. The fly isn't even asked if he wishes to go.

It were well if toads were content to feed only upon such insects as annoy or injure us; but not so. How often have bee-keepers seen this demure old batrachian quietly sitting at the entrance of the bee-hives, enjoying the cool evening breeze, and lapping up the belated worker-bees as they come heavily laden from the field! We can wish he wouldn't do it; but then, when we remember that he has been honestly employed all day, and remember, also, how good honey is, we can hardly visit him with our wrath for this one overt act. Candidly, the toad does so much good that I would not pronounce sentence of death, even if he does gulp down a few worker-bees. On the whole, he is a valuable friend, Nor would I raise my hives two or more feet from the earth to avoid him. I would the rather fence out the toads by a low close board fence, should he gain too great a fondness for my pets of the hive.

But, how about the stings? Is the toad so quick that he receives no sting? Nay, verily; no bee-keeper will believe, as I once heard a person just stung by a bee say, "Lightning can not strike a bee so quickly as not to be stung." If, then, the celerity of the act does not preclude the sting, how is it that the toad does not run fairly yelping at the first capture? I think he either has very little feeling in his throat, or else, finding the bee so to his taste, he has become callous to the sting. From observations that I have made I think the former must be the case. The past summer I have examined two throats of toads killed, the one just after and the other soon after it had been feeding upon bees. In both cases, just as many stings were found fastened in the toad's throat as the toad had been noticed to capture. Thus we know that the bee does sting its enemy. I did not find inflammation. Thus we must believe that the throat is proof against the venom of the bee.

During the last of May, while visiting at my brother's, we saw many bees captured by king-birds. The bird would fly from some perch, capture a bee, and then fly back to the perch and swallow the prize. Bertie, my little boy, shot one of the birds, and found several worker-bees, not drones, in the bird's stomach. Who shall determine, in this case, whether or not the bird is stung? We shall try to the coming summer.

A. J. COOK.

Agricultural College, Mich., Oct. 19, 1886.

We are very much obliged indeed, friend C., for the facts you give us in the above. I do believe it is a Christian duty to teach our children not to fear toads; and, can't I add, even snakes? I find it almost impossible to keep our boys from killing almost every striped snake they find on our grounds; and since I have begun to get somewhat acquainted with them, I confess I rather like to see them gliding about so noiselessly. Should we not all learn to go slow in judging hastily these neighbors around us—the dumb neighbors as well as those that can talk and reason?

SHIPPING EARLY QUEENS FROM THE SOUTH.

DO BEES HEAR?

MR. BRUBAKER, on page 484, writes very disparagingly of getting queens early in the season. He says he has never been able to do it earlier than he could do it himself. Well, I think the reason is this: He orders (and so does almost every one else) of the "extensive breeders" of the South. Those who are well advertised have a large number of customers, and have had for several years past, and are most *prominently* known as Southern breeders, and consequently they receive all, or nearly all, orders made to the *South* for queens—more than they can fill by June 1st, probably, in most instances, while the beginner gets but few orders, and has many more queens than he gets orders for—just as good queens, too, as those sent out by the "extensive breeders" of the South. I think if parties wanting queens early will act on this suggestion, they will be much more likely to get them. As to sending queens from the South to the North, early and late in the season, I can say this: In 1885, March 10, I mailed H. H. Peters, Leighton, Pa., a queen that was safely delivered on the 6th day after mailing. It snowed and sleeted heavily on the 11th here in North Carolina, the day after it started. I also sent queens the same spring to Nebraska, April 4; arrived all right; to R. L. Taylor, Lapeer, Mich., March 28, 5 queens; they also arrived safely. This spring I mailed queens to Ohio, April 17; Canada, April 25; New York, April 17th; *all* arrived safely. I see no reason why queens can't be mailed safely to almost any point in the U. S. after April 15th any year. I for one have, and will do it again, if it be the Lord's will.

Out of 66 hives, spring count, I put sections on only 3, the others being run for bees and queens, for sale. One of these yielded me 20 lbs. of nice capped honey, May 20; sections, filled and capped, were taken off the other two, May 24. The honey-flow for this section began April 26th, and closed May 25th last spring.

JONES ENTRANCE-GUARDS.

These will not always confine queens. I had a swarm issue this spring that had a guard over the entrance. It confines drones all right.

DO BEES HEAR?

If not, why do they set up the call that they give when hiving, just as soon as they decide to accept the proffered home, and begin to enter it? Is it natural that any thing which has no hearing should be endowed with a voice—*as a rule*, such as bees, for instance? Of what effect to them would it be without the benefit of hearing one another? How do they locate the hum of bees when robbing one another, and come in numbers so quick, if they can't hear? ABBOTT L. SWINSON, 71—72.

Goldsboro, Wayne Co., N. C.

Friend S., it seems to me the evidence is pretty strong that bees *do* hear.—Very likely you are right about getting early queens from the South; but there is this one thing very certain: the man who has a supply on hand, ready to fill orders in March and April, will have a wonderful business when people get to find it out. See page 305, 1886.

NOT ABOUT BEES.

DR. MILLER TELLS OF HIS VISIT TO THE HOME OF THE HONEY-BEES.

AFTER making a visit to my old mother in Pennsylvania, I started to the N. A. Convention at Indianapolis, and stopped on my way at Medina. I suspect many of the readers of GLEANINGS would like to know something about Mr. Root at his own home, for I find my own family have been very much interested in hearing about it. Since I was at Medina before, he has got into his new house, and I was delighted to find such an elegant home. My own home is of a more common sort, and the surroundings by no means such as I would have if I were in a more money-making business; but I do enjoy seeing my friends have nice things. I remember but two things that I wanted to see different about Mr. Root's house. I wanted to see the fine brick walls covered with *Ampelopsis Veitchii*, and perhaps he may yet start some plants of this grand climber, for it takes some time for it to grow. There is, in the minds of some, a prejudice against this class of plants, which is, I think, not well founded. They think that the vines keep the brick walls damp, and thus hasten their decay. If they did do so, their great beauty would be a considerable compensation. But I think it quite possible that the reverse is the truth. The close foliage makes a dense covering, which protects the wall against the injurious heat of the sun and the beating rains, and it is quite possible that the little feet by which the plant attaches itself to the bricks serve to some extent as roots, and draw moisture from the wall. The other thing was this: As I went up to my bedroom I passed through a hall having a floor of wood of natural color, and up a flight of stairs, if I remember rightly, of ash, finished in natural color, and the good taste was shown to have no carpet to hide this beautifully finished wood; then on coming to my bedroom the first thing that met my eyes was a door, one side of which, instead of showing the natural grain of the wood, was covered over with paint, and then the attempt was made to imitate the natural grain by graining with paint. That riled me. To the educated eye, the plainest grain of even pine wood is preferable to the best graining; and in this case it could hardly have been because the door was made of pine, for in the very same room the beautiful inside shutters were nothing in the world but plain pine finished natural color. I hardly see why people will persist in getting up these shams in the way of graining, when the genuine grain of the plainest kind of wood, finished in the cheapest manner, looks so much better. Besides, when the graining is marred or knocked off, there is nothing left but to cover it all over again; whereas, the natural grain can not be knocked off; and when marred it can easily be brightened up again. So far as I could judge, the grounds about the house are laid out very nicely, although, of course, the trees and shrubbery have not had time yet to attain any great size.

I was a little disappointed, when I asked about some of the things planted on the lawn, to be told that the gardener could tell me all about them. I thought it was Mr. Root's business to know all about them himself, so as to enjoy them. But when I passed beyond these grounds to the market-garden he could answer all my questions, and many that I didn't ask. And, oh what growth! But when I pushed my foot through the finely pulverized loam I didn't wonder. Things couldn't help but grow in such soil. On this ground, stand still a few majestic maples, gorgeous in their rich autumn dress, which Mr. Root thinks must give way for more garden stuff. I hope the women-folks, with their natural love for the beautiful, will enter so earnest a protest against such ruthless vandalism that Mr. Root will be compelled to stay his hand.

I will not attempt to describe the great factory and the many happy faces I saw there. The lunch-room is quite an institution; and with its clean and well-cooked food it is no great wonder it should have an extensive patronage from others besides those in the immediate vicinity. Mr. Root has adopted the sensible and humane plan of having his family take dinner and supper sometimes, if not always, at the lunch-room. While he was eating dinner, some one came and told him that a customer wanted some celery, and there was none at the store. In a little while Mr. Root finished his dinner and started for the celery-patch, perhaps an eighth of a mile distant. I followed, puffing, after, for Mr. Root is great on a tramp, and I am getting pretty fat. Soon he came to the long rows of celery, beautiful to look at, but not so nice to straddle over; but I straddled after him, although there seemed some little danger of being split in two thereby. To my relief, after straddling two or three rows he stepped on the summit of the others with something like an apology in an undertone for so doing. Then with a spading-fork he dug up the celery, trimmed off the roots, went and washed it at the pump, took it to the store, and, after weighing, got ten cents for it—hardly half the price I have seen the same amount sold for. I said, "Why didn't you let somebody else do this?"

He replied, "The boys were not through dinner yet, and I didn't like to ask them."

"Then let the customer wait," said I.

I don't remember exactly what answer he made. As one of the proprietors of the publisher of GLEANINGS, (for have we not all a kind of proprietorship in GLEANINGS and its founder?) I protest against his frittering away his time in things of this kind that could be done just as well without him, and wherein his time will not net him more than perhaps 50 cents a day. It would be better for Mr. Root and the world at large if he would get it into his restless head that it is his religious duty to cultivate a little wholesome laziness, and save himself for a longer life instead of being cut off in the midst of his usefulness. I am very glad to believe that in his son and son-in-law he has very worthy assistants. If I am not mistaken, Ernest bids fair, with his candid way of viewing things, and his keen habits of observation, to make a better bee-keeper than even his father was. If it were not for trenching on private ground, I should like to speak of Mr. Root's matronly wife and interesting family, but I forbear. I said to little Huber (he's a regular perpetual motion), "We have two cows at our house." He promptly replied, "Fudge! Uncle Hen has more than that."

One of the last things I saw as I took my way to the station was one of the $4.00 wheelbarrows. I stopped to examine it carefully and admire its beautiful appearance as well as nice construction, and between you and me it's better than my cheap one; but I wouldn't gratify Mr. Root by saying so.

Marengo, Ill., Oct. 19, 1886. C. C. MILLER.

Friend M., I want to protest a little. You do not understand me, and nobody seems to understand me, unless it is my good friend Mrs. Chaddock. It won't wear me out at all to get out in the lots after celery; on the contrary, I am, almost all day long, wanting some excuse for tramping out over the lots, and especially during this beautiful fall weather. If somebody should come for fifty dollars' worth of chaff hives, you would not see me budge an inch; but if he were in a great hurry, and anxious to get away at the very earliest possible moment, John and Bert and Mr. Horn, and may be some more of them, would go without their dinners entirely to help him off—I am sure they would. Now, celery-growing is one of my latest hobbies; and they all know that, if somebody should come and want five cents' worth of celery I should just be delighted at the chance of getting it for him. Why, I would take off my hat, make my best bow, and invite him to go down into the field, if he looked as if he could tramp; and instead of being worn out by exercise, I should get a new lease of life. When the weather is fine, and things are growing nicely, I am generally in such a hurry to get out into the fields I finish my dinner before any of the rest. During this dry fall weather we are engaged in introducing the "New Agriculture" down in the creek bottoms. We have routed the frogs, and the rich dark muck, in the bottom of the holes formed by the old creek-bed, shovels out just as nice as can be. Then we take a horse and stone-boat, and gather all the stones and rubbish that can be found anywhere in the neighborhood, to fill these reservoirs. Another thing I enjoy down in the fields is getting acquainted with my brood of Light Brahmas. They now roam over the greater part of our 18 acres; and when they see me down there they know there is going to be some fun and something good to eat.—In regard to the real wood itself, instead of the most artistic graining, I am with you exactly. When I build another house it shall all be natural wood. Our painter said he could make graining that would never crack and peel off; but there is one of the doors that is so cracked up that it looks "awful" already.—The reason why I could not give you the names of the plants in the dooryard was because I can not encumber my mind with so much. For instance, the names of the greater part of them are like the plant you mention — *Ampelopsis Veitchii*. Now, if plants with such names as these opened up an opportunity of teaching people who are out of work how to make a livelihood right at home in their own gardens, as does celery culture, then I might love to go into it. Just now I am heart and soul engaged in the work of telling people *what to do*, and *how to be happy while doing it*.

STEALING PROPOLIS, ETC.

HOW TO GET SIX GALLONS OF HONEY FROM A FOUR-GALLON KEG.

I PLACED a number of old rotten hives under the shade of a cherry-tree in the apiary, in order that the bees engaged in that particular line of business might, instead of a trip a mile or more to the gum swamp, help themselves to the large supply of propolis which lined the cracks and crevices of the hive; and seeing a number at work a few days since, I closely watched the *modus operandi* of obtaining and placing it on their so-called baskets. The particles bitten off are passed alternately to one and the other, and the amount apparently deposited on each is kept as equal as if weighed and measured with mathematical precision. On the wing, I suppose their line of flight would be uneven if a greater weight were placed on either side, or only one basket were loaded. Like Cowper's unwilling race-rider, the same weight was placed on either side to make the balance true.

BEES STEALING FROM EACH OTHER.

Hundreds of times I have noticed bees robbing, or stealing honey; but they are not confined to this particular article, for I saw an unusual theft perpetrated. A bee alighted where there were several others at work, and at once commenced to nibble away at the hard mass, but without success, and, raising its head, stood motionless for a moment, seemingly in deep thought. A bee near by, and just ahead, whom she was eyeing, had nearly obtained a load of the wax, and was turning round and round with head down, pulling at a small particle, nearly detached from the mass, when suddenly, and as quick as thought, she seized one of the basket-loads, and, with mandibles and fore legs, tore it from the basket of the industrious worker, and appropriated it to her own use. The thought occurred to me, "Did they belong to the same colony?" If it is the queen that imparts the peculiar scent whereby each worker recognizes the inmates of that family, would it not be remarkable that this scent is retained for hours, on the body of workers in the sun and wind, and continue after contact with, and frequently enveloped in, highly scented blooms?

BEES SHEDDING.

Something new I learned lately; and as a new edition of your A B C is frequently issued, with changes of old and the addition of new matter, I contribute it for the enlightenment of your readers. On a visit this spring to a man living 10 or 12 miles from me in the hills, and who wished to sell his bees, I learned something new. His bees were in plain board hives, with cross-sticks through the middle, and placed at convenient points about the yard, under trees and bushes. He knew as little about bees as he did of comets and the other heavenly bodies, and measured the knowledge of others on this and kindred subjects by his own meager supply. He was at my side as I examined the gums as best I could, making remarks as to its condition at each inspection. Turning a hive bottom upward (a colony of hybrids), I said to him, "Some of the bees in this hive are very pretty, and finely marked. They are beautiful."

"Yes," he said, very seriously and impressively, "you will find that all my bees will be as fine as these when they *all* shed off in the spring."

I made no answer to this unpublished information; but as we traded, it occurred to me that he thought this was the nail that drove the trade and induced me to take the bees, that all the bees would be finer-looking when they "shed off" in the spring. You have noticed old bees shed off, or that had rubbed off the hairs, or fuzz, of their bodies (thorax) passing between the combs, and in various other ways; but this shedding, as the horse, cow, and other animals, will be an entirely new idea to you.

BEES PACKING.

Esquire D. and a neighbor were discussing the productiveness of swarms hived in different ways and at different times, when his neighbor, becoming very enthusiastic in praise of a swarm placed the year before in a 4-gallon keg, said, "They went to work—never saw bees do better, and the first time I robbed it I took six gallons of nice strained honey."

"How's that?" inquired the 'squire? "You hived them in a 4-gallon keg, and took 6 gallons of honey from them? That don't seem possible."

"Well, the fact is, it don't look possible, and wouldn't be with any thing but bees; but you must remember they are the beatingest things on earth to pack. We took 6 gallons of nice honey."

Murfreesboro, Tenn. W. P. HENDERSON.

Friend H., the fact you give us about bees stealing from each other's legs is something quite new. You ask if they belonged to the same colony. Now, perhaps you may think I have got a little wild when I say that recent observations convince me more and more that bees do not recognize each other by scent, but by actions and behavior. I have seen a nucleus made up of bees from three or four different colonies, that would, in just a few hours, defend themselves from robbers as perfectly as any old colony; and it is my belief that they would have repelled robbing bees from the same colony they had been taken from but a few hours before. The scent may have something to do with it; but I am satisfied that it is only a small factor, even if it has any thing to do with it at all. If this is true when bees meet each other in the fields, they have no means of telling whether they are from the same colony or not.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

CAN MELILOT BE USED FOR PASTURAGE?

IS melilot, or sweet clover, good for hay or feed for stock in any shape? If so, do you think it will pay to raise it for that purpose? Will stock eat it as they would rye or any other grass? A friend of mine has a piece of land which he would like to seed in some kind of hardy clover for pasture, and I think melilot is about the only variety which will stand our climate, as it is subject to drought. My bees are swarming again. Hives are full of brood, some even in the sections. In some cases I find 16 frames full of brood; no honey in lower frames; just about two inches along top-bars of upper. I am using eight-frame Simp. hives. What shall I do with them? M. BROERS.

Gonzales, Texas, Sept. 27, 1886.

Melilot has been used to some extent for pasturage, but stock will rarely eat it if they can get any thing else. There is a particular stage in its growth, say when it is one foot or eight inches high, that the stalks are tender, and much like ordinary clover. At just this stage, some horses and cattle will eat it with avidity. As a rule, however, it has been abandoned as a forage plant.

LEAVES FOR PACKING; OTHER MATTERS.

I have just about finished packing my bees, leaving them on their summer stands. I have used forest-leaves, and believe them decidedly preferable to chaff or straw, inasmuch as they will not entice the mice. Chaff or straw usually has more or less grain mixed through it, and, of course, this is most inviting to the little fellows.

As I take a retrospective view of things, a few points come up which I feel like mentioning. I have wondered if others have been through what I have in introducing queens. In one instance, upon removing the lid at the time a queen was emerging, to my surprise she immediately took wing. I was fortunate enough to catch her, however, at the first grasp. At another time I selected eggs from a fine queen from which to rear a queen for a colony that had repeatedly rejected the queens I had sought to introduce. The time of exit for the queen, from egg, had come, so I went to see her swing open her portal; and, what was my astonishment to find her making her way out at the base of the cell—a long fine one! Well, I thought, what kind of a queen is this? and as I could not brook delay I used my penknife to emancipate her "royal highness," and out came—a majestic graceful form? No; a flirting, mincing worker. Of course, I had read of such things, but this was my first experience. I want to add, this colony has a queen now that is still laying, in spite of the cold days and nights.

240 LBS. OF EXTRACTED HONEY PER COLONY.

My bees have averaged me 240 lbs. to the colony (spring count). I have extracted most of my honey, and marketed it, in a clear white-glass jar, manufactured by the Independent Glass Co., Pittsburgh, Pa. Pints cost only $8.50 per gross. They hold 1¾ lbs. I notice Mason is making a flint jar now. The old Mason jar, with the green tinge, was not a desirable receptacle, as it gave the honey a bad appearance. The jars I speak of have a glass top which screws down upon a rubber. With all, they make a very nice and attractive parcel. I have received 30 cts. for every jar, so you see my bees have brought me in roundly. In all this I remember Him who is the source and measure of all God's goodness, and I send up most gratefully the incense of praise. **Frank C. Blount.**

Lawndale, Ill., Oct. 16, 1886.

Friend B., I have never thought of the reason you give for preferring leaves to any thing else for packing; namely, that there is nothing in the leaves that mice would want; and I believe reports seem to indicate that there is no better absorbent known than forest-leaves. By the way, forest-leaves are coming much in favor, not only for protection, but as a fertilizing material, and to make hard clay soils light and friable.—There is another advantage in using fruit-jars for honey—they are always worth to the purchaser all they cost, and I have many times wondered why they were not used in place of the common jars and bottles that are of little or no use after the honey is consumed. Jars made of flint glass are rapidly coming into favor.

CAN A BLACK QUEEN BE THE MOTHER OF A PURE ITALIAN QUEEN AND OF A BLACK QUEEN?

What is it? Well, I am going to leave it for you to name for me. I have invited all my bee-keeping friends here in New Bedford to see a queen I raised this year, the last of June. They say they think I have a curiosity. In the first place I had a black queen in a swarm that came to me two years ago, and I hived it June, 1884. Last May she cast a swarm the 24th, 25th, and 26th, with Alley's queen-trap attached to the entrance. The swarm went back twice. The third day the queen got hung trying to force her way through the perforated zinc, and, as a result, died. I felt sorry, for she had been a very profitable queen. She left one queen hatched, one still in the cell. May 28th I divided the colony. I liberated the confined queen, and let her run with one-half the bees. I put the liberated queen and the second half into another hive. No. 1 has a black queen; has filled both the upper and lower stories with bees, and I shall get some surplus from them. No. 2 has a queen, large and prolific, with three distinct yellow bands, and is as handsome as any one wants to look at. I have six hives, all Italians save one. I closed the hybrid drones in until after she was fertilized. Her young bees have been examined by the best judge I can get here, and not the least trace of hybrid can be found in the hive, all the old ones having died out.

July 21st I took a small handful of bees and gave them two frames of brood, one with eggs. They raised a queen, which was purely mated. When the queen was laying I gave her bees a frame of brood, and another partly filled with empty comb. August 21st she had four frames well covered with bees and brood. Two days ago I gave them one more frame of empty comb, with 3 or 4 lbs. of sealed honey, and one frame of fdn. They have six frames now, and a prospect of doing well. This is my first nucleus. If I can get them to cover six frames I can carry them through the winter all right, and have a good start in the spring. I think a great deal of fall queens.

What is a pound of new comb worth when the selling price of honey is 25 cts. per lb., and 50 lbs. is considered a good yield per hive?

New Bedford, Mass. **Chas. L. Eldridge.**

I think the queen you mention, with three distinct yellow bands, is, without question, at least partly black blood; and having met an Italian drone it is nothing strange that her worker-bees are all of them well marked. No doubt many queens have been pronounced full blood whose worker-bees were one-fourth or more black bees; and, on the other hand, many have, very likely, been pronounced hybrid that were full-blood Italian. The reason why the two queens, although from the same mother, have given queens so unlike, is probably in a line with the fact that many Italian queens, after having met a black drone, produce worker-progeny, some black, some three-banded, and some apparently hybrid.—Your concluding query, I presume, refers to the value per pound of new white comb to fit into section boxes. If it were not for the additional trouble of fastening in these pieces of white comb, compared with putting in foundation, I should think they might be worth $1.00 per pound, or even more.

MAKING HIVES OF PLASTER OF PARIS.

I see that John Craycaft, of Altoona, Orange Co., Florida, has got started on this road. Why not adopt my invention? I have been using cement hives for six years. I mold mine out of plaster of Paris. I have about 100 of them in use. I have some that I have wintered six years in succession. They are warmer in winter and cooler in summer; are moth-proof as well as robber-proof, and cheaper than any wooden hive in the North. The lower story needs to be molded large enough to take in a box so as to leave a chamber of two inches all around and under it to fill with chaff; then put chaff on top of the swarm. They will winter well in this cold latitude. In the South, the cement is all that is needed. They need no paint, and have given good satisfaction where tried. They can be molded so as to fit any frame.

I started in the spring with 70 colonies, and increased to 120, mostly by artificial swarming. I have taken 2500 lbs. of extracted and 1500 lbs. of comb honey in 1-lb. sections. The extracted is selling at 9 cts., and comb 12½ cts. The season opened up as well as I ever saw. I had a good flow until the drought set in, which was about the middle of May. They gathered but little foul honey, and are in good condition for wintering.

New Sharon, Ia., Oct. 7, 1886. GEORGE BRIGGS.

No doubt, friend B., plaster of Paris will answer excellently for bee-hives, but I think most of us would find it more expensive in the end, aside from the fact that it is so easily injured. I think I should want my hives painted for looks, if for nothing more; and painted plaster of Paris looks about as unsightly as a thing can well look, after it gets bumped and punched, and the corners are knocked off.

A QUEEN'S LOVE FOR HER OLD HOME.

Will you kindly throw a little light on a small matter that puzzled me somewhat in my bee-keeping this summer, and that seems to me to be rather unusual? I give you an extract from my diary:

Monday, Aug. 2, 1 P. M.—I caught and killed an old queen in black colony No. 6. At the same time I caught and caged a handsome, young, prolific Italian queen in colony No. 4, standing about twenty feet north-east from No. 6, both hives facing south. I put the caged queen on top of the frames in No. 6 till evening. At 7 P. M. I found the bees quiet about the cage. I removed the drone-trap (Jones's), smoked the bees and let the queen run in at the entrance, according to J. E. Pond, page 530. I replaced the drone-trap, and thought all was right. Friday, Aug. 6, I examined Italian colony No. 4, and was pleased to find 15 royal cells in different stages of development. Saturday evening, the 7th, I examined black No. 6, to see if my young Italian queen was all right, but I could not find her. Monday afternoon, Aug. 9, looking over Italian No. 4, I was surprised to find not a vestige of a royal cell left, but found quite a number of royal cells started in black No. 6. Tuesday morning, the 10th, with the help of my son, I examined Italian No. 4, and found the queen back in her own family again all right. I then went to black No. 6, cut out all royal cells, and gave Italian brood, which perhaps I might have avoided, as I found very young larvæ, apparently from eggs left by the young queen. About the end of August I introduced her to a hybrid stock in the same way, about 40 feet west. She was received, and remains quiet. F. CLARE.

L'Original, Ont., Can., Sept. 27, 1886.

The circumstance you relate is not common, yet instances of similar character have appeared in GLEANINGS at different times. As the queen was, I should judge, fertilized in No. 4, she had no difficulty, after leaving the black colony, in finding her old home.

A VISIT TO M. H. HUNT'S APIARY; THE ADVANTAGES OF WINDBREAKS.

On the 13th and 14th of the present month I made a visit to the apiary of Mr. M. H. Hunt, of Bell Branch, and was so well pleased with his manner of handling bees and honey that I have decided to follow his mode of manipulation until I am *certain* that I have found something better. My experience in wintering in single-walled hives is decidedly in favor of good windbreaks. Fourteen colonies (9 weak, 5 strong), with good packing and windbreak, all came through in good condition; of 13 colonies, all strong in bees and stores, with good packing and no windbreak, 12 died before spring opened; and I think there could have been no difference in their stores, as it would not exceed 60 feet from one corner of my apiary to the other, and all had natural stores. I shall start this winter with 25 colonies, all strong in bees and stores, and hope to be able to make a good report in the spring. ISAAC T. GOULD.

Corunna, Mich., Sept. 27, 1886.

DOES DAMP AIR RISE?

I am ever so much pleased with those bee-feeders. As soon as I got them unpacked I had to sell some of them to my neighbors for bread-pans and custard-dishes, and I don't know what else they were going to use them for. I want to ask you one question: Does foul or damp air settle to the bottom a bee-house, or does it rise to the top? This question I have never got solved. Almost every one disagrees on it. My ventilator at the bottom of is one inch in diameter, coming up through the flour. My ventilator at the top is a five-inch pipe; and what I want to know is, how near to the flour does my upper ventilation need to come down? BENJ. E. RICE.

Boscobel, Wis., Oct. 4, 1886.

Friend R., your question is not an easy one to answer. Damp air is certainly lighter than dry air at the same temperature. In a bee-house, however, the bees warm the air at the same time that they dampen it by the moisture from their breath, and this damp warm air, of course, rises, and would pass out of the ventilator if there were room enough for cold air to come up through the floor and take its place; but a passage one inch in diameter would by no means admit of this. Where the tube can be attached to a stovepipe, so as to get up a considerable draft, it is usually run down to within a few inches of the floor, that it may draw up the cold air and take it away. In this case it would also remove any carbonic acid that might have been given off by the bees and settled at the bottom. Carbonic-acid gas is a great deal heavier than common air, and sometimes collects over the bottom of the floor, making the air poisonous. If your ventilator is not connected with a chimney or stovepipe, I would have it reach just through the ceiling.

THE HEDDON HIVE.

I spent a day at the convention at Indianapolis last week, and was very much interested in the proceedings, and in examining the various articles exhibited. I wanted to see that marvelous hive of Mr. Heddon's. It is a beauty, but I do not think it will suit us in this climate. We can not afford to have a summer hive and a winter hive. We must have one that will answer for both. For that purpose we must have a chaff hive. I see no way of making a chaff hive out of the Heddon hive. It may be very fine for summer, but will not do for wintering on the summer stands. I know nothing better than your chaff hive for that purpose. I have 26 of them in my apiary now, and they work nicely. The only objection to them is, that they are inconvenient in the summer, when you have the top part full of wide frames, and want to get into the lower part. How do you manage it? What is the reason you can not construct a case like the Heddon surplus-case, or like the surplus-case that was on the hive exhibited by Bro. Demaree, and have it to fit into your chaff hive, so you could lift out the case, sections and all, at one time? Can not such a thing be made so it will work? J. H. LOUDEN.

Bloomington, Ind., Oct. 18, 1886.

Friend L., the difficulty of getting out the lower frames when the upper ones are full of sections has never been remedied; that is, there has never been a remedy suggested that will not make the hive more complicated, and more troublesome to work than to have it as it is—at least, that is my opinion. Of course, you can have Heddon crates, or crates of other styles, to lift out, instead of lifting out the wide frames, and we now make them with crates instead of wide frames when preferred; but you will find it is some trouble to lift a couple of crates when they are filled with honey, and put them back again. The difficulty, however, is not so very great as might be imagined; for few honey-producers are in the habit of disturbing the brood-nest when the bees are at work in surplus-receptacles.

A FRAME HIVE PRECEDING LANGSTROTH'S.

C. H. Lake, of Baltimore, was at the Elkton, Md., Fair. He, among an extensive exhibit there, had the effects of Colvin in the apiarian line, and made same startling statements. He had a hive presented by Otto, king of Greece, to Mr. Colvin, in use in Greece long before Mr. Langstroth's invention of the "frame." This hive opened on one side, from which "frames" were pushed in on rabbets, or cleats. There were three sets of frames, of about 8 or 10 each, above each other, with ⅜-inch space between and at the ends. He also read quotations from old manuscripts, describing these hives, and also showing that separators were in use several centuries ago. If any of this is new to you, I wish you would write to him for his evidence, or go and see these curiosities and papers.

CHLOROFORM WILL CONQUER.

I have had a hybrid colony queenless for more than a month, which has resisted all the methods of introducing queens until yesterday. Three fine queens have been killed, after prolonged efforts with each. At the Elkton Fair, Mr. Lake had an albino queen-cell to hatch, and I came in possession of the queen. The next day at noon I presented the same to this hybrid colony, which at once began to tear her to pieces. I seized and caged her. I then dropped into the bottom of this hive—a 3-frame nucleus, about one teaspoonful of chloroform; placed the queen in, and closed the hive up. I waited until all became quiet—about 10 minutes, when, on looking in, a good share of the bees were on the bottom-board, anæsthetized. I found the queen, held her in my hand until she could walk around pretty well, when I placed her on a comb, and again closed up the hive until the bees were well recovered, when I carried the colony out to its old location, and allowed the bees out to enter. The queen to-day is all right.

S. W. MORRISON, M. D.

Oxford, Pa., Oct. 11, 1886.

We are fully conversant with the facts you mention, friend M., and I believe Mr. Langstroth knew all about it after his frame and hive were invented, for he and Mr. Colvin were very intimate friends. You will notice Mr. Colvin's name mentioned several times in Mr. Langstroth's book. These Grecian hives were never made practicable, and the simplicity of the L. frame and hive, compared with them, is what gave bee-keeping such a great impetus at the time of friend L.'s invention.—The matter of chloroform has been before our journals, and has been a good deal experimented on. Sometimes it answers nicely, as in your case; but at other times it does not. I do not know whether anybody uses it regularly now for introducing queens or not.

HOW TO PURIFY EXTRACTED HONEY; HONEY IN SODA-WATER.

Can you tell how to purify extracted honey, so there will not be any sediment? I could sell all my honey at a good figure to the bottling-works in Grand Rapids, for making a flavoring syrup for soda-fountains, but they fail in filtering it in any way so that it will be clear. They tried, but there would be a sediment of a darkish color that spoiled it for use. This is a matter of no little importance to the bee-fraternity, as it would make quite a demand for honey, and that to make a good temperance drink. Perhaps A. J. Cook or others could answer through GLEANINGS.

Grandville, Mich., Oct. 9, 1886. J. S. WARNER.

Friend W., straining your honey through the cheese-cloth which we recommend and sell for the purpose, we think will remove every thing that can be objectionable. If your honey is very thick, it will have to be warmed to pass through readily. But in case this straining should not be sufficient, you can filter it through a bag made of coarse flannel. The particles of flannel will catch every particle of the finest dust that may be in the honey. If Prof. Cook has had experience in straining and filtering honey, we should be very glad to have him tell us about it.

WHAT RENT SHOULD BE PAID FOR THE USE OF LAND FOR AN APIARY?

Would you please inform me what is customary to pay in establishing an apiary on somebody's else land? Does the owner of the bees give a share, or pay money? I am thinking of taking part of my colonies away from home, but do not know what would be right to offer. Does the owner of the land generally have any thing else to do but to watch the bees that they be not molested, for instance?

Greenville, Ill., Oct. 12, 1886. GUSTAVE GROSS.

Friend G., it is a pretty hard matter to give an answer to your question, or, in fact, any question of the kind. It all rests on circumstances so much that the best we can say is, "As the parties may agree." If the owner of the land proposes to watch the bees, and keep away thieves, he should have a little more pay on this account. If he also proposes to look after swarms, and hive them, then his pay should be still better. So you see it depends on how much responsibility each party proposes to take. Sometimes a pound of honey for each colony left on the premises is considered sufficient rent. If that is not enough, say two pounds or more, or even five pounds, where swarms are looked after, etc.

A TREATISE ON FLORIDA, AND ITS RESOURCES.

To those of your readers interested in Florida, I take the liberty to say, that altogether the best book that has ever been written about the State is

Dr. Smith's. Dr. Smith is professor of geology at the University of Alabama, and was a special-census agent of U. S. A. His report gives all the bottom facts about Florida—the geology, physical geography, constituents of soil, growth, elevation, rainfall, adaptation of soils to particular crops, drainage, etc. Of course, it does not give the details in regard to the honey product and some other things, such as are furnished you by Hart and others, but all the fundamental facts are there. It forms a part of the U. S. census. I do not know where a copy is to be had; but any one who wishes to know all about Florida ought to begin with it. J. A. GOREE.

Tuscaloosa, Ala.

QUEEN-CATCHERS, AND CLIPPING QUEENS.

I have used an implement similar to Klimitz's queen-catcher for some time. I am in the city, and it will not do to run over town to take swarms out of neighbors' yards or from the shade-trees in the streets, so I clip the queens' wings. To catch up the wings by the fingers, with the feet always in motion, and then clip the wing, risks too much; danger comes in of getting a foot with the wing. Letting the queen rest on the knee is not always safe either, so I have a small sack made of mosquito-netting, which I pass over the open end of the cage; and as the queen runs into the sack out of the cage, I have her in the sack with her tail toward the opening. I withdraw the cage, lay it down, and turn back the ends of the sack, holding the queen in the sack by her head and body with the left hand; as soon as the wing is exposed I clip exactly what I want, and then release her. It takes a little longer time, but it is sure, and not the least danger of injury does the queen incur, and this is the main point. The cage I have used has ragged wire edges, which catch the bag. Mr. K.'s cage is better.

HONOR TO WHOM HONOR IS DUE.

Give everybody credit, is my motto, if it doesn't cost too much. Let Mr. Heddon have credit for his hive—it is a good one; Mr. Jones for his—it is equally good; let Mr. Heddon have all the credit the pollen theory is worth, and let Mr. Clarke hibernate the bees. Let all the army of reversible-frame inventors be pleased with themselves, and last, but not least, let Mr. Perrine have the credit of being the "Father of Adulteration of Honey." I believe that is what he claimed at the late congress in New Orleans. All I ask is, credit for the money I send. S. C. BOYLSTON.

Charleston, S. C.

Friend B., your suggestion in regard to handling queens is good, but I think I should prefer to handle them with my naked fingers. They sometimes bite spitefully, it is true; but I am not afraid the queens will injure me, and I am pretty sure I shall not injure the queens. Your suggestions about giving credit are also good.

A LETTER FROM ONE OF OUR AUSTRALIAN FRIENDS.

I am interested a little in bees. I have ten hives. I commenced with one, a chance swarm, which came along in December, 1884; and since reading your A B C it seems more wonderful. You Americans can do almost any thing. I do not know that our country can produce honey like yours; but I have been told, since taking an interest in bees, of some of our farmers in the country districts having as much as six tons of honey in one season from bees kept in all sorts of boxes. Nearly all the native trees here blossom—gums, box, and acacia—and just now in winter I see the Tasmanian blue gum (*Eucalyptus globulus*) is coming into blossom, and will continue until August. I have two Woodbury and eight Langstroth hives, or the same size as your Simplicity hives. The Bee-Keepers' Society here decided on that size. I see you have the cold to contend with, but we do not get snow here, and there is not more than two or three days wet, or weather when the bees can not work, and I notice now they are busy bringing in pollen. Sometimes we have four or five fine sunny days; the geraniums and marigolds I see bloom all the year round. Ours is not one of the best places for bees. It is very open, or plain, and not many trees.

Braybrook, Victoria, Australia. WILLIAM DABB.

We think Australia is making rapid strides in bee culture. We have filled quite a number of orders from there for machinery, etc. Thanks for your kind letter, friend D. I do not see why Australia should not give as good results as America. Are you sure the capabilities of your country have been as fully brought out as ours have?

STINGLESS BEES IN AUSTRALIA.

A correspondent from Queensland sends us the following:

Your correspondent, Mr. Henry Stewart, is not quite correct in stating, p. 208, GLEANINGS, that the stingless bee is found only in South and North America, and not in the other continents; at all events, we have a stingless bee in Queensland in two varieties, very similar in appearance, but their nests and combs are different. I send you herewith a pressed specimen of the bee for microscopic examination. They are such insignificant little things that I hardly think it would ever be worth while to cultivate them. The whole yield of a large colony is only about a quart. Their combs are certainly not constructed of wax, although it looks much like it. I tried to melt up a lot once, but got only a dark-brown sticky mass, which, however, proved a source of immense attraction to the bees in my apiary; for although there was an immense profusion of honey-flowers at the time, they seemed to give them up entirely, and devoted their whole attention to carrying away the brown sticky mass, and plastering it all over the inside of their hives. As I didn't want it there, I buried it, and so forced them to go about what I considered a more profitable occupation.

As I have started writing I may mention a curious circumstance which has just happened in my poultry-yard. A tiger cat got in one night, and, for apparently the pure delight in murder, killed two geese, two ducks, and one sitting hen and one of her chicks, leaving five unprotected orphans. The mother had laid only about a dozen eggs before she commenced to brood, and she had a sister in the yard that was just about to begin to lay. Well, next morning this young pullet with her fiery-red comb commenced to cluck, cluck, like a brooding hen, called the chickens to her, brooded over them at night, and has, in every respect, performed a mother's duties to her nephews and nieces, although she has never yet laid an egg. Formerly, if one of the chicks came near her while they were being fed she would peck at them furiously, but now she won't touch a morsel till they are all fully satisfied.

What a pity we can't teach the bees to behave in a similarly charitable manner to their relations who happen to fall into misfortune or distress!

ÆNEAS WALKER.

Redland, Queensland, Australia.

Many thanks for the samples of stingless bees you send us, friend W. I will forward them to Prof. Cook. Meanwhile I would say to our readers that the bees are about the size of a common house-fly — perhaps a little smaller. If a whole colony yields only a quart, however, we shall have to regard them more as a curiosity than any thing of practical value.

REPORTS ENCOURAGING.

A GOOD REPORT, AND FROM TEXAS TOO; FROM 108 TO 150, AND 12,000 LBS. OF HONEY.

I HEREWITH send you my report of this season's operations with my bees. I commenced the season with 108 colonies in medium condition. The spring was backward, and they had used all of their honey before there was sufficient new honey coming in to support them. Swarming was cut off to a great extent, but I got an increase of 42 colonies by natural swarms. I had about 80 swarms in all, but I put back all afterswarms and prime swarms that came out after the 20th of April.

The honey-flow commenced about the 25th of April on guajilla and continued about 20 days; the last 8 or 10 days being from cat-claw. The cat-claw honey-flow was cut short over 2 weeks. It usually lasts over 3 weeks. A very small caterpillar webbed up and destroyed the blooms. There has been no surplus gathered since to amount to any thing. I have taken 5000 lbs. of comb honey in bulk, and 7000 lbs. of extracted honey. I have sold it all out; also about 1500 lbs. that I bought. I also took about 500 lbs. of 1-lb. sections. The summer and fall have been so dry that there is no chance for any more surplus this season. My bees will go into winter with plenty of stores, and strong in bees. Our county is about the best in the State, taking one year with another. I have been here 4 years, and there has been no failure of a honey-crop yet. There are so many different trees and plants that suit all kinds of seasons, that there is not much danger of failure.

4—D. M. EDWARDS, 108—150.

Uvalde, Texas, Oct. 9, 1886.

FROM 43 TO 56, AND 1600 LBS. OF HONEY.

I wintered 43 without the loss of one stand. I increased to 13, and got 1600 lbs. of honey. My bees are in good condition for winter, and are working heavy now.

B. J. WARDAN.

Plainville, O., Oct. 5, 1886.

$40.00 FROM ONE COLONY, BESIDES THE INCREASE OF THREE.

I started with 6 good swarms and 2 nuclei this spring. I increased to 30, and sold 5. I took 646 sections. My 25 remaining colonies are all good and strong, with plenty of honey. From one of my hives I sold $20.00 worth of bees and $20.00 worth of honey, and have 3 good colonies left which are worth $10.00 per colony, making $70.00 from one colony. Who can beat it? I got 18 and 20 cts. per lb. for my honey.

Connotton, O. CHARLES E. HARDESTY.

FROM 98 TO 128, AND 12,000 LBS. OF HONEY.

I commenced the season of 1886 with 90 colonies and 8 nuclei. I increased to 128, and have taken 12,000 lbs. of honey—11,500 lbs. extracted, and 500 comb. My honey is all sold; the average price 6 cts.

Shellsburg, Benton Co., Ia. ROBT. QUINN.

NOT LARGE, BUT SWEET.

My honey-crop was not large, but it is very sweet. I have 50 colonies, and have taken 1400 lbs. of nice section honey. Bees are in good condition, and well supplied for winter.

W. H. MARTIN.

Dunkirk, O., Sept. 20, 1886.

FROM 4 TO 9, AND 850 LBS. OF HONEY.

I had four colonies, spring count. I increased them to nine, and extracted 370 lbs. of light honey, 360 lbs. of dark, and 120 lbs. of comb honey. Total, 850 lbs., all very nice. I am feeding sugar for wintering.

ROBT. J. LATHERS.

Inkster, Mich., Oct. 2, 1886.

FROM 6 TO 11, AND 600 LBS. OF HONEY, AND BLACK BEES AT THAT.

I had six hives of blacks at the beginning of the present season. I increased to 11, and obtained about 600 lbs. of comb honey. There is no basswood in this country. Buckwheat sown for fall pasturage was a failure, and bees made no honey after Aug. 1st. I have wintered a few bees two winters, and lost none. I never fed any, and don't know how, nor have I protected them from cold in winter. The first winter I left the interstices between the top-bars open. Last winter I placed some rags in the upper story.

F. A. MINOR.

Marshfield, Mo., Oct. 5, 1886.

50 LBS. PER COLONY.

I do not see how I could get along without GLEANINGS. I think every one who keeps four or five stands of bees should take it.

As our honey season is over I will give you my report for 1886. I commenced in the spring with 40 colonies, and increased to 47. I worked for honey, not increase. I have taken 50 lbs. per colony, spring count, about an equal quantity of comb and extracted. I use the extractor to keep swarming down. Bees have made no surplus honey since the 15th of July. My bees have plenty of stores for winter. Honey is mostly all sold at 8 to 12½ cts. per lb., according to condition and quality. I sell my honey all at home. I make it my rule, when I sell to one of my friends, that, when he gets out, he will know where to come and get more.

Bucklin, Linn Co., Mo. J. W. SWITZER.

A GOOD REPORT FROM AN A B C SCHOLAR; 156 LBS. PER COLONY, AND 25 INCREASE.

I herewith send you my report for this season. I began with 8 swarms, in good condition, and two very weak, which were used for queen-rearing. From the above 8 swarms I received 1250 lbs. of honey—1170 lbs. in 1-lb. sections, and about 75 lbs. extracted, making 156 lbs. per colony. Besides this I now have 30 good swarms, of which I bought 5 swarms and gave one to our preacher and one to another neighbor, making 27 swarms in all. I attribute my success mostly to the teachings of your A B C book and GLEANINGS, which I prize very highly, and wish you the best of success. Honest endeavor is always crowned with success, which latter I wish you with all my heart, as I never found a squarer man to deal with than

A. I. Root. If hives and fixtures have any thing to do with my success I must attribute it to the Heddon-Langstroth hive, which I use exclusively. I had one swarm which was queenless from Sept. 28, 1885, until June 2, 1886, which makes it 9 months and over. It came through with about a pint of bees. 4—**Jno. G. Rundinger, Jr.**—30.

Kilmanagh, Huron Co., Mich., Oct. 18, 1886.

WHAT SHALL BE DONE WITH "THE OLD-FOGY FARMERS" WHO ARE BRINGING DOWN THE PRICE OF HONEY?

We have had a good honey season here, and it is of the best quality. The flow has been steady. I have 100 colonies to go into winter; about 2800 lbs. of my crop is disposed of; about 2500 lbs. on hand. I have not taken all off yet. Prices are ruling low. I think it would be a profitable subject for discussion to decide what we are to do with a "set of old-fogy" farmers and "grandmothers" who persist in running to town and selling their honey for whatever a grocer may offer them, thus ruining the market for those "in the business."

Duncan, Ill. **W. H. Graves.**

Buy up the honey, friend G., from all these good people, and thus prevent them from demoralizing the market.

MY REPORT FOR THE SEASON OF 1886.

I began with 8 hives of my own, and bought three box hives, which I transferred into Simplicities. I purchased two queens of Jos. Byrne, with ½ lb. of bees with each. I turned loose these two queens and their bees, each into a colony, after taking out old queens. One of these hives and its increase gave me 133 lbs. of honey, and increased to 3 good colonies. I took, in all, 963 lbs. of honey—527 lbs. of this in sections. This honey was taken on pasture that does not yield 20 lbs. on an average to box-hive men. I attribute this success to using your Simplicity hive and implements—a superior knowledge of our pursuit gained by reading, and last, but not least, plenty of hard *work* to insure success. 3—**S. S. Lawing**, 12—24.

Henderson, Webster Co., Mo., Oct. 21, 1886.

SWEET CLOVER; A YIELD OF 70 LBS. PER COLONY, FROM THIS PLANT ALONE.

I send you a branch and flower of a plant that has no name. It produces honey of an excellent quality. Our honey crop would have been almost an entire failure had it not been for this plant. It blooms twice a year, but seems to produce more honey in the fall than in the spring. I have 70 hives of Italian bees, and did not get a pound of surplus this year until this plant bloomed about August 20. I have had a yield of 70 lbs. of extracted, and 50 of comb honey per colony, from a flower that I know to be from this plant. I have been watching the honey-yield from it for years, and have concluded it is one of the very best honey-producing plants we have in this locality. It is very abundant here, but is confined to the hills and cliffs. It is never found in the prairies. I am satisfied the yield this fall would have been much larger had it not been so wet and cloudy during September. **J. P. Caldwell.**

San Marcos, Hays Co., Texas, Oct. 12, 1886.

Why, friend C., it is a little funny if the plant you send has no name. It is the common well-known melilot, or sweet clover. I am very glad indeed to get such a good report from it.

NOTES AND QUERIES.

THE MOSQUITOS IN TEXAS.

TEXAS, or some portions of it, have a hard time this year. Great storms on the gulf coast, great drought in the interior of the State, besides the great railroad strike in the spring. Yet some counties are exempt, and Brazoria is one of them, except from storms. The gulf shore suffered a good deal, but crops are good. Cotton and corn are good. It is reported from some parts that bees did not do well; but my report shows 50 colonies in the spring, 60 in October, and about 700 gallons of extracted honey—not so good as last year, but good enough for a bad year. At present we are having a serious time fighting mosquitoes. They are so bad we can't pick cotton or do any thing else here, and we have to build fires to make smoke for our horses, and to milk cows. The animals come to the smoke and stand with their heads right in it. The stock cattle are in great big herds, sometimes 2000 in a bunch, to keep fighting the above pests. **John W. Ross.**

Phair, Texas, October 10, 1886.

A DRONE-LAYING QUEEN.

I have a colony of hybrid bees that have raised all drones in worker-cells. I took all the brood-frames out about three weeks ago, and gave frames of empty comb; but they are still raising all drones. Now, is the queen worthless? or is it the fault of the bees? **M. Gumbert.**

Heathville, Pa., June 24, 1886.

[Friend G., you either have a fertile worker or a drone-laying queen. See A B C, under head of Queen-Rearing, p. 202. A queen that continues to raise drones only is worthless, and she ought to have been destroyed a long while ago.]

IS IT THE NAMELESS DISEASE?

What ails one colony of my bees? For one month the bees at one stand have been fighting little black slick bees, perhaps a little over half the usual size for a bee. It seems to me they must be bred in the hive, for they always look as if they were nearly starved. On dissecting them I find there is no honey in them. The colony is moderately strong. **William Pickett.**

Deming, Hamilton Co., Ind.

[I think the trouble is the nameless bee-disease, friend P. The shiny-black bees generally have an emaciated look, something like a big black ant, and they usually have a shaking, tremulous motion when they move about.]

TRANSPLANTING SWEET CORN.

Noticing your enthusiasm on gardening, I will just say I like very much to have early vegetables. I shelled a small ear of sweet corn, made a hole in my hot-bed, and covered it up, to sprout, but before I could get it planted it was one mass of green sprouts and roots. Not wishing to throw it away, I concluded, by way of an experiment, to set it out, and, as a result, I had nice sweet corn for my dinner the 1st day of July. **Mollie O. Large.**

Millersville, Ill.

[Thank you, friend Mollie. I am glad to know that you love garden vegetables as well as honey-plants, and that you have a hot-bed. Now, I am much inclined to think that it would pay to have a small patch of early sweet corn started in the way you suggest, in a hot-bed or greenhouse. We could be away ahead of the market, and get a big price to reward us for the trouble of transplanting. Since you suggest it, I think I shall have to try it on a small scale next season.]

JOBBING OUT HONEY.

I am just about to start on my annual trip to job out my honey-crop in the neighboring towns.

Maysville, Ky., Sept. 2, 1886. W. C. PELHAM.

CAN BEES UTILIZE OLD BITS OF COMB?

Why would it not be economy to let bees have the old honey-comb to render up wax for themselves, instead of rendering it ourselves, to sell for 20 cts. per lb.? ALMON HOLMES.

Douglas Center, Wis., Sept. 30, 1886.

[Bees do use up old bits of comb to some extent, but I believe they generally use the old wax mostly, in place of propolis. I have, however, seen new combs made entirely from old black wax, fixed up, or, rather, scraped off from the bottom-board. When honey is coming in plentifully, there is usually wax enough secreted to furnish all that the bees require in comb-building.]

DOES SEALING HONEY ALWAYS PREVENT CANDYING?

I should like to use some clear glass jars for extracted honey, but I find that, if the honey candies, its sale is much reduced, besides spoiling its appearance. I am positive that, if honey is sealed while hot, it will not candy, as I have some in Mason jars a year old. G. WIEDERHOLD.

Yonkers, N. Y., Sept. 15, 1886.

[The matter you mention is one of the contested points, friend W. Our experiments indicate that honey, perfectly sealed up as we do fruit, when it is heated pretty nearly to the boiling-point, never candies until the sealing is loosened. But others say that some samples of honey will candy any way, no matter how carefully it is sealed up. I believe the tendency now is in favor of clear flint-glass jars for holding honey.]

WHY DO THE BEES SWARM IN AUGUST?

The goods came in good shape. The sections are nice, the nails are very nice, the labels and rubber stamp just please me; in fact, every thing is all satisfactory. Mr. Root, can you tell me the cause of bees swarming at this time of year? The last week in August I had four swarms come out, which is something I never had nor saw before.

S. W. GREEN.

North Greenwich, N. Y., Sept. 6, 1886.

[Friend G., I think that swarming in August is owing to a good yield of honey, and may be the good yield of honey you have had is what makes you so well pleased with the goods we sent you. Your orders were filled just as we fill all of our orders. Still I am very glad to know the things you received from us were satisfactory.]

TOBACCO COLUMN.

MY brother, F. H. Chapin, of Hinsdale, N. Y., has started me in a limited way in the bee-business, furnishing me a nucleus of Italians. My experience with them thus far is to try to subdue their angry passions as far as possible; and by watching his movements I saw the *smoker* had quite a cooling effect; and he also, my next-door neighbor, informs me of your generous offer of one of those articles to the person who quits tobacco. After having been an inveterate smoker for a good many years, I have now gone without it for over a month, and think I can stand the storm, as I have now got so I can sleep well, which I could not do after first giving it up. Mark price, if I should later break the contract. In looking into the top of a hive recently, I discovered a good many little small black ants. What effect have they, if any, on the colony?

Ashtabula, O., Sept. 9, 1886. A. H. CHAPIN.

See Ants, A B C book, page 10.

ANOTHER FRIEND TAKES THE PLEDGE.

I have quit the use of tobacco. If it is any pleasure to you to give a smoker to any one to abstain from the use of it, I will gladly receive one from you, and promise to pay $1.00 if I commence the use of it again. JOE HEAD.

Trenton, La., Sept. 15, 1886.

HAS USED IT FOR 30 YEARS.

After having used tobacco for over thirty years I have quit it, and never intend to use it in any form as long as I live. If you will send me a smoker I shall be very thankful, and will pay for it if I ever resume the filthy habit. WM. FINLEY.

Palma Sola, Manatee Co., Fla., Sept. 13, 1886.

GOING SECURITY FOR A NEIGHBOR.

I sold bees to a neighbor. He has smoked since he was 12 years old. I persuaded him to stop, saying you would send him a smoker. He has promised to stop, or pay you for the smoker if he begins again. I will go his security. D. W. MOORE.

Pelham Union, Ont., Can., Sept. 1, 1886.

IN BEHALF OF A NEIGHBOR, AGAIN.

I again come to you for a smoker on behalf of a neighbor of mine, who is now going into the bee-business. He was an inveterate user of tobacco, and now for two weeks has quit. He wishes a smoker; and if he begins the use again he will pay for it, and I vouch for him. L. B. POLK.

Selden, Ohio, Oct. 5, 1886.

ONE MORE JOINS OUR RANKS.

I have made up my mind not to use tobacco again; and if I do I will pay you for the smoker.

Wheatland, Mich. A. W. SPENCER.

HAS USED IT FOR 20 YEARS.

My father, who is about 59 years of age, has been smoking for 20 years. He promises never to use it again, and asks you to send him a smoker. If he ever uses it again he will pay you for it.

Oriole, Pa., Sept. 12, 1886. G. W. CLARK.

HAS BROKEN HIS PLEDGE.

I am sorry to say that John Goodhull has already broken his pledge, and commenced chewing. I inclose the pay for smoker. He, while plowing for wheat with a three-horse team, and working hard while hot, thought he could not stand it.

Williamson, N. Y., Sept. 13, 1886. C. S. ADAMS.

I understand that you send a smoker to all persons who have quit using tobacco. I have quit; and if I use it again I will pay for it. A. B. HEISER.

East Germantown, Ind.

One of my neighbors, Crawford Lentz, has quit the use of tobacco, and wants a smoker. Mr. L. is one of our good men, and means just what he says. He will pay double for the smoker if he uses the weed again. JAS. W. ROSEBERRY.

Kent, Mo., Sept. 28, 1886.

"A LITTLE FRIEND" HAS QUIT TOBACCO.

A little friend of mine, seeing your promise to give a smoker to any one who would quit the use of tobacco, has quit it. It has been three months since he used any. His name is George Williams. He asked me to write for him, and have you send the smoker to me; and if he ever uses it again I give you my promise to pay you for it myself.

W. A. SISTRUNK.

White Sulphur Springs, Ga., Sept. 18, 1886.

OUR OWN APIARY.

THE CONDITION OF OUR BEES FOR WINTER.

IT is with some reluctance, coupled with no little regret, that I inform our readers the exact condition of our bees for wintering. They are not, to my notion, in the best possible condition for the coming cold weather. A large number of our colonies are weak; not only that, but a large number have no young bees—one of the prime essentials for successful wintering. You ask, "Why this state of things?" I will explain. In the first place, you are all aware that we have had foul brood pretty generally in our apiary. In our efforts to exterminate its ravages we have burned up something like three or four hundred frames of brood. Such a drain as this in our apiary has necessarily left many of our colonies with a great number of old bees. Up to date we have had 60 cases of foul brood. In many instances the taking-away of the brood and honey, followed by 48 hours of starvation, seemed to so discourage the bees that they were slow to overcome the shock. When the treatment was applied in July and August, they recovered in a great measure; but as by far the larger part of the diseased colonies were treated in September and October, few if any of said colonies commenced brood-rearing again, even after feeding. In a word, then, this means that about one-quarter of our colonies have nothing but old discouraged bees. Besides these, about one-fourth more are, well—nuclei on four frames. Again, you will ask, "Why not double these up?" This we have done in a few cases; but there are two reasons why we shall not double up all. In the first place, these nuclei have valuable queens, none of which we value less than $2.00, and some are worth much more. To unite these nuclei would leave one surplus queen. On account of foul brood we can not sell or otherwise dispose of her. It is true, we could cage and place her over a cluster of bees. She might live a month or possibly two months; but as the ball of bees changes its position in the brood-nest in cold weather, her majesty might be left high and dry where she and her eight or ten bees could enjoy (?) a good freeze by themselves. There are about fifty colonies in our apiary that would stand uniting very comfortably, but that would leave a surplus of 25 queens, worth about $50.00. Taking every thing into consideration, we prefer to risk the queen and their colonies as they are.

There is still another reason for not uniting more generally. I told father that, if I could have a spell of warm weather, by feeding to stimulate brood-rearing I *believed* I could start foul brood in many of the colonies. That is, the germs of foul brood are in many apparently healthy colonies; but in the absence of brood in October, the disease was not apparent. If this be true, to unite very extensively would be apt to spread foul brood all over the apiary.

Now I confess I have taken a rather discouraging view of this existing state of things. Let us look at the other side for a moment. Those bees have all been fed up on sugar syrup of the best kind. They had been allowed to consume most of their natural stores before being fed, and it may be possible that they have consumed their diseased honey, if they had any. Again they have been contracted on as few combs as possible, consistent with sufficient stores, and given good wheat-chaff packing—in short, the best care we know how to give them, and so we hope for the best.

FEEDING AFTER DARK, BY MOONLIGHT AND LANTERN LIGHT.

As I have before stated, in consequence of foul brood we have been obliged to exercise extreme caution to prevent robbing. While examining colonies during warm days we have used the bee-tent with excellent success; but to feed by the aid of the tent, sunny days would be quite inconvenient, and well nigh impossible. If we waited till cold weather, that would be too late; besides, the bees would then be little inclined to carry the feed into the combs. It so happened about this time, Oct. 12th to 15th, we were having beautiful evenings, the moon being full at this date. The apiarist and myself availed ourselves of this opportunity, and fed all such colonies as were needy. We could not have had a lovelier time, no robbers to bother us or follow our feeding-cans about. We fed in this way about two barrels of sugar made into syrup. After the 15th, the moon did not come up till about 9 o'clock; and then as the bees still needed more feeding we were obliged to use artificial lights. As lamps go out too easily, we used lanterns. I gave the apiarist my large lantern, and then mother and I hunted around in the house till we found what we call Huber's lantern. I believe they are called "babies' lanterns." That was so insignificant I hardly thought it would do.

"But," said mother, "this is all we have in the house."

"Well," said I, "fix it up the best you can, and I'll try it."

I will explain to our readers, that the lantern in question is about 7 inches high, with a very small burner—a sort of lantern and night lamp combined. After I had worked awhile in the apiary I decided that it was just the thing. It was so small that it could be set down on top of the frames of the hives, or on a ledge of the hive. Its smallness, and, consequently, its using so little room, is why it is superior to the other lantern for night work in the apiary. We fed with lanterns about two barrels of syrup, and I do not think the lanterns caused us any more trouble than smokers in the day time. Not only did I do feeding by this kind of light, but I hunted queens, and performed various other little manipulations with the hives. Of course, on cool and chilly evenings it would not be policy nor even an advantage to work with the bees; but at that time of the year, when robbers are most troublesome during the hours of the day, a great many of the operations connected with the apiary can be performed easily and safely in warm clear evenings by moon light or lantern light. In the A B C of Bee Culture, under the head of "Robbing," the author lays special stress upon the fact that bees can be handled in the night time; but for some reason but few reports of it have come in, and those, I believe, of unfavorable character. The A B C recommends the use of a lamp and shade. As a lamp would require such careful handling, and besides would be likely to be blown out by a little breeze, I think a lantern would give results entirely satisfactory. If, then, our friends will use a lantern (which will stand tumbling about and all kinds of winds), I think they will find certain kinds of night work in the apiary a success. It is quite likely, on the first evening, if you try it, you will not look favorably upon it; but further trials, I think, will convince you that it is a nice time to do certain kinds of work.

Before closing this subject, let me say that the beginner with three or four colonies will probably never have occasion to resort to night work; but the extensive apiarist will find it a great convenience many times.

HANDLING BEES IN THE RAIN.

One day, while the apiarist and myself were working in the apiary, it began to rain—not very hard, but enough to drive all flying bees in, and to render the use of the tent unnecessary. As there was "lots of work to do" I said to Mr. Spafford,—

"If you are not afraid of the rain, I'm not. No robbers will bother us now, and we can just 'smash through' the work."

"All right," said Mr. S., with his usual pleasant manner; he always acquiesces when a new scheme is proposed.

We had on rubbers and old clothes, and so did not mind the wet. Although it rained nearly all day, we accomplished a good deal of work. We kept up a brisk circulation, and at night changed our clothing. On one or two other days we worked in the rain, but put on our gossamer coats. These, with suitable hats and rubbers, kept us nice and dry.

"How about the smoker-bellows?" perhaps you inquire. Our Clarks have been pretty well soaked once or twice, but I do not see but that they work just as well as before. "How about the bees?" possibly a beginner asks. Just as they always do—if any thing, a little more passive. It is a well-known fact, that, during a hard wind and rain storm, when a hive-cover has been blown off, the colony may be drenched, and no harm result to the bees.

I think hereafter, when a little rain comes and I have some work among the bees I want to do, I will put on a gossamer and rubbers, go about my work as before, and let it rain.

If I were to moralize upon this point I would say that any man who would be driven indoors from his work by a light rain ought not to obtain a full measure of success. Of course, if one is consumptive, or it be a heavy rain, then the circumstances are altered; and in either event it would be wise to seek shelter. But I said I wouldn't moralize, and Barney says my space is growing small, so I will leave you to reflect upon what good things I *might* have said.

FOUL BROOD UP TO DATE.

There is no foul brood in the apiary, nor has there been any for the last ten or fifteen days. If it were not this particular time of the year, we should feel that we had entirely eradicated the disease; but as brood-rearing has wholly ceased in all the hives, with a few exceptions, there is, in fact, nothing for the disease to work on. **Ernest.**

P. S.—As regards the appearance of foul brood, W. Z. Hutchinson's description of it (see p. 845) is *exactly* right. At least that is what our foul brood looked like. E. R.

The annual meeting of the Madison County (N. Y.) Bee-Keepers Association will be held at the Eagle Hotel, Oneida, N. Y., Wednesday, Nov. 17, 1886. A very interesting meeting will be had; all members, and those interested in bee culture, are requested to be present, as important business will come up for consideration. Officers for the ensuing year will be elected. The important topic—"How to make the business pay in a poor season like the one just past," will be carefully considered and discussed. All are invited to bring articles pertaining to bee culture for exhibition. F. L. Smith, Pres.
Oneida, N. Y.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, O.

MEDINA, NOV. 1, 1886.

Let all things be done decently and in order.—I. COR. 14 : 40.

We have, at this date, Nov. 1, 5979 subscribers.

OUR EXCHANGE DEPARTMENT FOR ADVERTISERS.

Inasmuch as many have called attention to the fact that our Exchange Department is being used for regular advertisements of things for sale, we think best hereafter to have that department devoted exclusively to articles for *exchange*—not for goods offered for sale in the regular way, and we greatly prefer that the friends would cut them down to five lines each and no more.

NO BROOD IN NOVEMBER.

Don't be alarmed, A B C friends, if your queens do stop laying during this month; in fact, it would be the exception if you do find brood; therefore you need not be in haste to call them queenless. Almost all colonies cease brood-rearing during October, November, and December. Very strong colonies, abundantly supplied with stores of every kind, many of them will commence brood-rearing about the first of the year, and it will then be kept up, as a rule, until spring.

BASSWOOD-TREES, GRAPEVINES, RASPBERRIES, ETC.

Perhaps there is no better season in the year for planting out the above, than this present month of November. We have a beautiful lot of basswood-trees growing on our cultivated and enriched soil. They have made a wonderful growth this season, and the roots are immense.

Our supply of Concord grapevines for shading bee-hives is not so large, but what we have are extra nice vines. This same cultivated and enriched soil has given us some extra nice Gregg raspberry roots. The Gregg and the Cuthbert are, perhaps, the most promising for both honey and fruit. We can furnish extra strong roots, 10 for 60 cts., or 100 for $3.00. If wanted by mail, 3 cts. each extra. For prices of grapevines and basswood-trees, see our regular price list.

ERNEST'S TEMPEST LANTERN.

After reading what Ernest has to say about working by lantern light in feeding bees, it occurred to me that you might like to know that the lantern he takes such a liking to is on our 50-cent counter. As they are quite small, I think there will be no trouble about sending them by mail at an expense of 10 cents extra for postage. At any rate, I will guarantee safe delivery at the above price. No accident can possibly happen to these lanterns, for they are made entirely of brass, and the oil-reservoir is filled with cotton. If you should drop it and step on it you might spoil your lantern, but you could not easily set any thing afire. They are made expressly to use in barns and stables. Fill the lamp with a heavy kerosene of good quality. They are not only safe, but they are durable and cleanly. No accumulations of smoke at the top can stop the draft.

LETTERS, FIGURES, ETC., BUILT IN HONEY-COMB.

At the Indianapolis Convention there were some exhibits in this line, probably superior to any thing that has ever been produced before in the world. Large letters that all could read the whole length of the great hall were beautifully worked out in honey-comb of pearly whiteness; also the figure of a mammoth queen-bee; and, astonishing though it may seem, words written in penmanship, even to the hair-strokes, were composed of honey-comb built by the bees. I believe the work was done by Mr. A. Cox, of White Lick, Boone Co., Ind. The exhibit of honey in globes, honey in the form of crosses, and honey in almost every shape imaginable, was wonderful. One end of the hall was literally filled with devices and implements. I do not know whether it suggested to Bro. Newman his museum or not; but it reminded *me* vividly of our museum.

FOUL BROOD; IS IT CONTAGIOUS?

At the Indianapolis Convention, one of the bee-friends related the following: He found three colonies in his apiary, affected with foul brood. Not knowing just what to do, he decided to look the matter up and treat them according to the most approved methods. Meanwhile the honey-flow stopped, leaving him with a large number of partly filled sections. In order to finish these sections he decided to extract a lot of honey from his heaviest hives, and feed it back; and before he knew it he had unconsciously or heedlessly extracted the honey from some combs in one of these foul-broody hives. The lot of honey containing some from this diseased colony was fed to 28 colonies before he became aware of what he had done. Now, then, what do you suppose happened? Why, every one of the 28 hives thus fed became at once diseased. I tell you, my friends, I would not go to bed, knowing that I had in my apiary a colony that had the real foul brood. Burn up the combs, brood, and honey, and do it in such a way that not one solitary drop or fraction of a drop of honey escapes where a bee may get a lick at it.

SENDING POSTAGE-STAMPS IN LETTERS.

We can always use postage-stamps where they are more convenient, and we can use them of any denomination, providing you do not stick them fast to your letters. The clerk who opens the mails insists that some of you are thoughtless enough to paste them right over the reading-matter before you send them off. We suspect, however, that it is not so bad as that, but that you are a little careless in putting them in the letter, as they are often sticky in warm weather. Do you wonder we sometimes get cross when we have to soak the letters in water over night in order to get the stamps loose? and then we have to put on some more gum before we can use them. Well, we don't mind this trouble very much; but when the water blots your letters so they can not be read without a good deal of fuss and trouble, we sometimes feel as if we should get mad, if it were not for the fact that we are Christian people here, and don't dare to. Now, then: When you send stamps again, please wrap them in a separate piece of paper, without any writing on it; and if it is not asking too much of you, don't wrap them up when they are sticky. Lay them somewhere in the sun, and let them dry first.

A NEW BEE-KEEPERS' MEDLEY.

Mr. E. O. Tuttle, of Bristol, Vt., has been, for some time back, busy in getting up a new medley of bee-keepers. The size is 8½×11 inches, and it contains pictures of 120 bee-keepers. A large portion of them are the same as appeared in our medley, published some ten or twelve years ago. Some of the pictures are very good, and a few of them are rather poor. The medley, however, ought to be well worth the sum of $1.00 to any one who is in the habit of reading our bee-journals. Among them we notice S. Corneil, R. McKnight, J. B. Hall, D. A. Jones, and W. F. Clarke, of Canada; in the United States we have Henry Alley, John Aspinwall, A. J. King, T. G. Newman, R. L. Taylor, Dr. C. C. Miller, Charles Dadant and son, H. D. Cutting, W. Z. Hutchinson, J. E. Pond, N. W. McLain, O. O. Poppleton, E. M. Hayhurst, L. C. Root, Mrs. Jennie Culp, Mrs. Chaddock, Mrs. Harrison, Oliver Foster, I. R. Good, M. H. Hunt, Norman Clark, P. L. Viallon, W. S. Hart, O. M. Blanton, and others. In the above list I have not intended to name those that are contained in our old medley. A descriptive pamphlet of 14 pages accompanies the photograph. They may be ordered from this office, or from friend Tuttle, as you choose.

HALF-POUND SECTIONS IN ENGLAND.

We find the following in the *British Bee Journal* for Oct. 14, under the title of "six-penny sections."

> SIX-PENNY SECTIONS.
>
> One of the most striking features of the show of Canadian honey at the Colonial Exhibition is the thinness of the sections exhibited, being only 1½ inches, the combs built therein being of worker thickness. Mr. Jones assures us from his own experience,—and it would be a bold British bee-keeper who would venture to compare his own with that of Mr. Jones,—that, contrary to what might be expected from the fact that three vertical surfaces (midrib and two sealings) are required in each inch instead of three in each 1½ inch, a larger harvest is obtainable of this thickness than of the greater thickness to which we are accustomed in the ordinary two-inch sections.
>
> In our issue of March 1, 1885, in an article entitled "Sections, Past, Present, and Future," we suggested the very same idea, pointing out that, by adopting the size of 4¼ x 3¼ x 1½, we could obtain sections of nominal half pound, which could be sold retail at sixpence each. The Canadian sections are as nearly as possible this size. We went on to say, "We venture to think, that, before many seasons are passed, a six-penny, or ½-lb. section, will be a recognized size."
>
> The British bee-keepers did not take to the idea, probably because the dealers could not supply the sections, and would not order them. Our Canadian cousins, however, took the hint; and while some of us are complaining of the slow sale of 1-lb. sections at 1 shilling, and have altogether neglected the nimble sixpence, they have been producing these pretty little sections, and here they are before our eyes. When we now see the very thing which was suggested to us in our own journal eighteen months ago, and hear that actually a larger harvest can be obtained in that form, it comes upon most of us as a complete revelation. We repeat, with great confidence, our prediction of March, 1885, and look forward to its fulfillment before another year has passed.

The show referred to by the editor took place Oct. 6. From the reports of the association I judge it must have been extremely interesting, especially as they had our good friends D. A. Jones, S. Corneil, McKnight, and others, of Canada. During the association friend Jones gave them a description of the Heddon hive. We notice there were present at the meeting, Wm. Raitt, of Scotland, and some from Switzerland. Of course, friend Jones had to have some fun going on, even if he was among long-titled people, and he improvised the following stanza:

Canada is a great country for honey;
It is there farmers and bee-keepers make lots of money.
Our bees extract nectar from flowers so sweet,
That all nations consider our honey a treat.

BEE - KEEPER'S GUIDE;

Or, MANUAL OF THE APIARY.

13,000 SOLD SINCE 1876.

14th THOUSAND JUST OUT!

10th THOUSAND SOLD IN JUST FOUR MONTHS!

5000 Sold Since May, 1883.

More than 50 pages, and more than 50 fine illustrations were added in the 8th edition. The whole work has been thoroughly revised, and contains the very latest in respect to bee-keeping. It is certainly the fullest and most scientific work treating of bees in the World. Price, by mail, **$1.25.** Liberal discount to dealers and to clubs.

A. J. COOK, Author and Publisher,
13-23 Agricultural College, Mich.

SAY! the **ACME PAPER-HOLDER** holds all sorts of small things, as papers, letters, almanacs, magazines, pamphlets, cards, etc., and does it quick, before they get lost, stolen, blown away, or the baby gets them. By mail, 10c.; two, 15c.; five, 25c.; twelve, 50c. Agents wanted.

4 H.-P. ENGINE FOR SALE.

A Bargain for the man who is in need of a First-Class Engine and Boiler.

This is one of B. W. Payne & Son's Eureka engines, the same that we advertise in our catalogue. It has run 3 months since it was new; has had a 10-foot galvanized-iron smoke-stack added, and is in perfect running order. The man who is holding it had to put in a larger one to meet the demands of his trade. The price of a new engine and boiler complete, no stack, is $275.00; but to make a quick sale we will sell this one with the stack for $225.00, free on board cars at Higginsville, Mo.

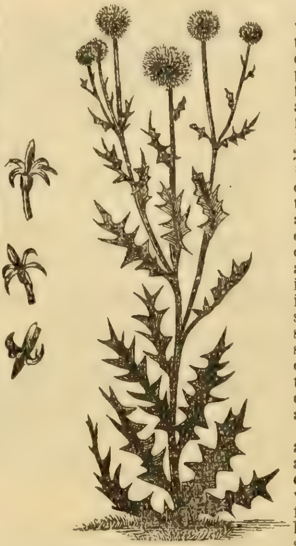
The Chapman Honey-Plant.



In accordance with a previous notice in bee-periodicals, I am now prepared to fill orders for the seed of the above plant at the following prices: ½ oz., $1; 1 oz., $2; 2 oz., $3; 4 oz., $5; ½ lb., $8. One oz. contains from 1600 to 1800 seeds. On account of extreme drought my stock of seed is limited, and persons ordering will be served in rotation. The seed should be sown in the early spring, and general directions for cultivation will be given on each package.

This plant is not an obnoxious weed, and is as easily eradicated as clover. Having carefully watched its habits of growth, and its honey-producing qualities for the past six years, I believe those who commence its cultivation in a liberal way will be better pleased than by commencing with a small quantity of seed. It has been tested by prominent bee-keepers all the way from Vermont to Nebraska and Ontario. We refer to the report of the committee appointed by the North-American Bee-Keepers' Association held at Detroit in 1885. The committee reported at the Indianapolis, Ind., convention held Oct. 12th to 14th, and their report will be found in all bee-periodicals publishing the report of that convention.

Write all orders plainly, and give your postoffice address in full.

H. CHAPMAN,
Versailles, Cattaraugus Co., N. Y.

LUTHER GRAY, Orlando, Fla.

40-Horse-Power Engine for Sale.

Our new automatic cut-off 90-horse-power engine is now driving the machinery in all our buildings. Now, we want to dispose of our old 40-horse-power engine which has done such faithful work for us for the last eight years. It is a standard plain engine, Lord & Bowler make, 12x20, with a 9-foot balance-wheel and a 6-foot fly-wheel. We will offer it, put in good repairs, for $350.00. We will throw in the stone upon which the bed-plate is bolted, free of charge. For further particulars, write us. Whom shall we hear from first?

A. I. ROOT, Medina, Ohio.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—The market is good for all grades, and sales are large, receipts are very good, and prices are steady with a firm feeling.

White clover,	1-lb. sections	13@14
" "	2-lb. "	11@12
" "	½ lb. "	14@15
Dark	1-lb. "	10@12
"	2-lb. "	9@10
California,	2-lb. "	9@11
Extracted,	white clover	6@7
"	dark	4@5
"	white sage, California	5½
"	amber "	5
Beeswax,		20@22

Nov. 10, 1886. CLEMONS, CLOON & CO.,
Cor. 4th and Walnut St's, Kansas City, Mo.

BOSTON.—*Honey.*—Honey is selling well, but would sell better if weather were colder. No change in prices. BLAKE & RIPLEY,
Nov. 10, 1886. 57 Chatham St., Boston, Mass.

NEW YORK.—*Honey*—Comb honey is not moving as fast as we expected, which is probably due to the warm weather we have had of late. Now the weather has set in cold, and we expect an increase in the future. California extracted, white sage, and sumac honey is moving off rapidly at unchanged prices. THURBER, WHYLAND & CO.,
Nov. 10, 1886. Read and Hudson Sts., New York.

ST. LOUIS.—*Honey.*—We have nothing very encouraging to offer on honey. This month, California parties have been here with lots of comb honey, selling at 10½@11c, and some outside parties are selling white clover in 1-lb sections at 11½@12½c. Common comb honey, original packages, 9@11; southern extracted or strained honey, bbls., 3@4; choice in cans, 5½@6c. *Beeswax*, as it runs, 20c; selected, 23. Trade is dull in general.
M. B. WESTCOTT & CO.,
Nov. 10, 1886. 108 and 110 Market Street.

CHICAGO.—*Honey.*—Sales have been better during the past two weeks than at any time during the past season. But prices are, if any thing, lower; 10@11c for good white honey; 12@13c for fancy, in less than one-pound frames. Extracted, dull, at unchanged figures. *Beeswax*, in fair demand at 23@25c. R A BURNETT,
161 So. Water St., Chicago, Ill.

CLEVELAND.—*Honey.*—The market continues dull for all grades of honey, and prices a trifle lower. Best 1-lb. white honey is selling at 13@13; 2 lbs., 10@11. Dark and old stock not wanted. Extracted holding at 6c, but no sales. *Beeswax*, 25c.
Nov. 9, 1886. A. C. KENDEL,
115 Ontario St., Cleveland, O.

MILWAUKEE. — *Honey.* — This market continues very steady on prices for honey, and demand only fair. Choice white comb, in 1-lb. sections, 12½@13; same in 2-lb. sections, 12@12½. Extracted, in one-half barrels and kegs, white, 6½@7; same in bbls., white, 6c; in bbls., dark, 5@5¼. A. V. BISHOP.
Nov. 10, 1886. 142 W. Water St., Milwaukee, Wis.

CINCINNATI.—*Honey.*—There is a lively demand for table honey in square glass jars, and the demand for nice comb honey is very good. Demand from manufacturers is slow for dark grades of extracted honey. The range of prices for extracted honey is 3@7c per lb. on arrival.

Nice comb honey brings 12@15c a lb. in a jobbing way. There is a good home demand for *beeswax*. We pay 20@23c a lb. on arrival.
CHAS. F. MUTH & SON,
Nov. 10, 1886. Cincinnati, Ohio.

FOR SALE.—White-clover comb honey in Root's 48 1-lb. cases, at $5.00 apiece, case included, and delivered at depot, on receipt of cash. G. S. FOX,
Mitchellville, Polk Co., Ia.

FOR SALE.—Having harvested 30 bbls. of honey, I offer to dispose of what is left at 6½c net (barrels average 530 lbs.). The bulk of this lot is clover honey. Those who order first have choice of variety.
H. W. FUNK (Box 1156), Bloomington, Ill.

FOR SALE.—500 lbs. white-clover honey in 1-lb sections, put on board cars here in nice glassed (Heddon's 12-lb.) cases for 14c per lb. ready to ship on receipt of orders. G. O. ANDERSON,
Marshville, Oceana Co., Mich.

NEW YORK.—*Honey.*—Sales of comb honey the past month have been good, and prices fair. Honey from the West is coming in more freely than was anticipated earlier in the season. Present quotations are as follows: Fancy white, in 1-lb. sections, in neat and clean packages, 13@15c; same in 2-lb. sections, 11@12c. Fair to good, in 1-lb. sections, 11@13; same in 2-lb. sections 9@10. Buckwheat in 1-lb. sections, 9@10; same, in 2-lb. sections, 7@8½. Extracted, white-clover, in kegs and barrels., 6@7; white Cal., in 60-lb. cans, 5@6; Cal. comb, in 60-lb. cases, 10@14. McCAUL & HILDRETH BROS.,
34 Hudson St., cor. Duane St., N. Y. City.
Nov. 13, 1886.

ADULTERATING COMB AND LIQUID HONEY.

IS THERE SUCH A THING AS MANUFACTURED HONEY AND MANUFACTURED EGGS?

THE following letter was forwarded to us through the kindness of the publisher of the *American Grocer*, with an expression that I should answer it for publication:

> *Editor American Grocer:*—Will you be kind enough to give me information about manufactured honey, if there is such a thing? I think you have published articles on it in your paper, but I have failed to see them. If you will give me the numbers of your paper that have contained the articles, and where I can get them, or answer this through your paper, you will oblige. Also, is there such a thing as manufactured eggs? J. H. WHITE.
>
> Bridgeport, Ct., Oct. 26, 1886.

In response to the above request we sent the following reply, which was in the *American Grocer* for Nov. 11:

We are very glad indeed to answer the portion of the above that refers to our branch of agricultural industry, especially as the honey-business is getting to be a branch of no mean pretensions. When liquid honey sold at from 20 to 25 cents per pound, and glucose, or corn syrup, was worth only from 5 to 6 cents per pound, there was a great temptation toward adulteration; and eight or ten years ago it was probably a fact that a great portion of the liquid honey in glass jars and tumblers to be found in our markets, was more or less adulterated. Now, however, when liquid honey is sold at from 8 to 10 cents retail, and 5 to 7 cents wholesale, there is but little inducement to adulterate with glucose, especially as the quality of glucose at all fit for the purpose is worth from 4½ to 5 cents per pound. On this account I believe there is but very little honey to be found on our markets now that is adulterated. Perhaps I may add, that a good many mistakes and a good deal of uncharitableness have arisen from the fact that both pure honey and pure glucose (or corn syrup) are, chemically speaking, pretty nearly the same thing; namely, grape sugar—glucose being grape sugar manufactured expressly for the purpose of making it retain a permanent liquid form. In California, excellent honey is now sold in quantities as low as 3 cents per pound. This state of affairs makes it more feasible and more likely that glucose should be adulterated with honey, than that honey should be adulterated with glucose. The present low prices of cane sugar, also, have been discouraging to those engaged in adulterating sweets.

Bee-keepers have also been accused of feeding their bees glucose, and then taking it from the combs and selling it as honey. This foolish piece of slander on our bee-keeping brethren was probably first started by some one who did not even know that bees do not *make* honey—they simply *gather* it. The act of storing it in the cells does not change it in any respect. If you feed the bees sugar syrup, it will be sugar syrup when it is taken away from them. The same is true of glucose or any other substitute for honey.

We now come to artificial comb honey.

The only way in which it is possible to put a spurious article of comb honey on the market would be by feeding the bees glucose or some other substitute for honey; and there would be a greater probability of this being done, because comb honey usually commands a half more in price than liquid honey, were it not for the fact that the bees must consume a very large quantity of honey or other sweets to enable them to secrete a very small quantity of white wax from which the comb is made. This latter fact has been so well proven by the experiments of hundreds of bee-keepers, that the practice of feeding liquid honey, in order to make the bees store comb honey, is now, I believe, universally abandoned. As an illustration: When the honey season closes in the fall, most bee-keepers find themselves in the possession of more or less sections of nice, marketable comb honey, with cells not quite finished. A large apiarist frequently has a ton or more of such unfinished sections. A little feeding would enable him to finish these out, put them on the market, and get his cash, instead of waiting a whole year to have them finished. On this account it would be extremely convenient to feed enough pure honey to get them finished. Well, *sometimes* this will pay; but we have all found out that so large a quantity of honey must be given to the bees to get just a little put back into these unfinished combs, that even this has been mostly abandoned.

Our last point is in reply to the newspaper statements that were so widespread a year or two ago, to the effect that our comb honey on the market was made by machinery, and that neither comb nor contents ever came from a bee-hive. So widespread was this falsehood, that in our journal of Nov. 1, 1885, page 738, I offered $1000 to anybody who would tell me where such spurious comb honey was made. No one has ever given the information, neither has one ounce of manufactured comb honey ever been forthcoming. It is a mechanical impossibility, and will, in my opinion, remain so. It is true, bee-keepers use largely what we call "comb foundation;" that is, sheets of beeswax stamped with the impress of the base of the honey-comb. The bees use this, draw out the cells, and fill them with honey; but as these sheets are always pure beeswax (in fact, a substitute that will answer even tolerably has never yet been discovered) there is nothing really spurious about it. I hardly need add, that the above slanderous report in regard to bogus comb honey was very damaging to the bee-keeping industry. It probably obtained wider credence because one Prof. Wylie, some years ago, started it by what he termed a "scientific pleasantry."

In regard to the artificial eggs, I believe this will be a feat still more difficult to accomplish than making artificial honey-comb, especially if these artificial eggs are *expected to hatch*. Some of the newspapers have jocosely declared that such eggs would hatch, but that the chickens did not have any feathers on them, the invention not yet being sufficiently "perfected," etc.

The adulteration of our food products is indeed a terrible wrong, and I believe the bee-men are as much in earnest about it as are the dairy-men; and if there is any thing we can do as a class toward putting these thieves and blacklegs behind such strong iron bars that they will *have* to be honest, we stand ready to do it; and thousands of us are willing to give our voices, our strength, and our money toward helping to punish the guilty. But let us have charity for each other, and be slow about rushing to the conclusion that everybody is a rogue except—

Your humble servant.

FIRST-CLASS EXTRACTED HONEY.

CAN IT BE RIPENED BY ARTIFICIAL MEANS SO AS TO EQUAL THAT RIPENED IN THE HIVES?

IF it were not a question of great importance, and one with which I have experimented a great deal, I wouldn't occupy your valuable space and my own limited time in controverting what I believe to be one of the few erroneous doctrines of our highly respected friend Muth. I refer to his teachings, that first-class extracted honey can be obtained by taking it from the hive before being capped, or "ripened," and ripening it afterward by atmospheric action. I am aware that this is one of friend Muth's old, old hobbies, but one which either will not fit all locations, or else he is mistaken in regard to the character of first-class extracted honey.

Fifteen years ago I procured two tin tanks, with gates at the bottom, holding 450 and 550 lbs. respectively. My honey-house was arranged just right for the atmospheric curing process; and while the effect was to greatly improve the raw honey, it did not, and I believe can not, ripen it to that sweet, oily flavor and consistency found in old comb honey. Endeavoring to carry the same principle further, I purchased 400 one-gallon stone jars and stored my honey in them, piling them on top of each other with sticks between, to give free circulation of warm dry air over the comparatively broad surface of these small receptacles. This carried the principle to greater perfection, but by no means to equal the extracted honey I am producing at the present time. My 1886 crop of extracted, alone reaches about 30,000 lbs., nearly all clover and basswood, as, owing to the drought, our fall flowers yielded but little more than winter supplies, and I am, as usual, jobbing it out to bee-keepers and consumers in 50 and 100 lb. lots; and I sincerely believe, that, should I begin filling orders with honey ripened *a la* friend Muth, I would soon hear a buzzing in my ears, and my rapidly growing trade would as rapidly diminish. I believe I have learned the fact, that extracted honey is depreciated in price, as compared with comb honey, mainly because it is rarely found to be its equal in quality.

I have just been reading friend Blanton's wail, on page 851; also your foot-notes, where you ask if extracted honey at 5 cts. per lb. can not successfully compete with cane sugar? I should like to answer, by saying that I haven't the least idea that it would compete with cane sugar at even 2½ cts. per lb. You will remember, that years ago I was abused by some enthusiastic bee-keepers for predicting this state of affairs, which is confirming what I then declared; viz., that honey could not be produced at a price to ever make it a successful competitor of cane sugar, except for the small amount demanded for sweet sauce and table ornament; that, hence, it never would become a staple, always remaining a commodity, which could easily oversupply the demand. Does not Mr. Dorthman's sad account, found on page 857, verify both of my propositions, so far laid down in this article?

REVERSING.

I notice, on page 858, that friend Hawk has failed to accomplish what he desired, either by brood-comb crowding or reversing. As I have had much experience with both methods, he reports just what I should expect to result from crowding brood-combs together. But if Mr. Hawk will continue the inverting system, especially if properly combined with contraction and alternating of the brood-chamber, in two horizontal sections, till he strikes the right system of manipulation for his location, I think I may say that I know he will succeed in devoting his brood-chamber to brood, and his surplus cases to surplus honey, which we all so much desire, and that, too, with the least amount of time, trouble, or exposure to robbing-bees.

GERMAN BEES.

On page 859, I see that Ralph E. Gould, who is evidently a practical honey-producer, has been testing the comparative merits of the German, Syrian, Italian, and other races of bees, and reports the same as I always expect to see, with the best strain of German bees in the hands of a bee-master; viz., that, for the most and nicest surplus comb honey, no bees known to man will excel the German variety. I am always pleased to see these bees receive the just praise that their many superior characteristics warrant.

JAMES HEDDON.

Dowagiac, Mich., Nov., 1886.

Friend H., I did not understand Mr. Muth to claim, particularly, that honey thus ripened would be equal to the best ripened in the hives, so your opinions may not necessarily differ, after all; but what friend Muth told us will be of great advantage, certainly to those who have unripened honey on their hands. But I agree with you in thinking the bees ripen it better, certainly, if not cheaper than we can by any artificial means. Friend M. sends out very nice extracted honey. Now, right here comes in a point: Do you permit the bees to cap all the honey before extracting, or do you wait until they commence capping? You may have given your experience in this matter before, but it was probably some time ago, and we should like to hear it again. And, by the way, will you give us your latest experience in the operation of extracting the honey with the least amount of labor consistent with getting the very best article? Where one works for extracted honey, how about reversing combs? and how much reversing is expedient? I did not expect extracted honey was going to affect the price of sugar very much; but I did think, and I do think, that when people will begin to reason this way: "Why, at the price it is now offered, it is not much if any more expensive than the syrups and sugar we use," then nice honey will come pretty near being as staple as butter.—I know the German bees have been called by a few individuals better than the Italians, for comb honey; but I do not know that I have heard anybody claim that they would give even as much where the extractor is used.

A HORSE OF WONDERFUL INTELLIGENCE.

MY BROTHER IN CALIFORNIA ALSO GIVES US A SKETCH OF BEE-HIVES IN THE GROUND.

BROTHER AMOS:—I have owned one of my horses almost three years, and have only just found out how intelligent she is. The forehead is full, and I have known she was almost human ever since I owned her. She had been raised to herd cattle until I got her. The other afternoon my two cows got off to their old home, about four miles, and Dolly and I went after them and got them started back to where the road forks out each side of the farm. The cows would get to the forks and run down one, and I would have to run and head them off, and then they would run back the other road, and run into the timber. I then got off and left Dolly standing in the road, while I went into the underbrush to get them out. Dolly saw me start them out, and she then gave a loud neigh and started off on a gallop. I thought she had gone home and left me; but on getting out to the forks of the road I found her standing on the opposite forks, with her ears back, ready to drive them on to the road leading home. The cattle are very gentle; and if they do not go to suit her she will put back her ears and bite at them. She does not bite hard, but just gets their skin between her teeth, and pinches, and they soon learn to skip out of her way. If they turn out of the road she goes out after them, and heads them off. Several people want to buy her, but they have not money enough. To say that I was astonished, would be speaking mildly of her great intelligence.

While out riding, looking for my cattle last week, I found a bee-cave a short distance from the house. Saturday afternoon I took my hired man, and we went down into the ravine and dug the dirt away, and got out about 150 lbs. of nice honey. They had made it in a hole that the rains had tunneled out. The first rain would have washed them all out. There are several others around. The ground seems to be a natural place for bees. The sides they had all waxed nicely, and 'twas cool down in there the hottest of weather. They are nice Italians, and not cross. I put a hive with comb foundation for them to go into.

Later.—Now, the laugh comes on me right here. As I went down to see about the hive I left to get the bees in, I found I had made a mistake, and the original swarm was *there yet*, and we had taken up another cave, about one rod below, thinking it was the one I found. Now the question is, What shall we do with the honey? In San Diego it is not worth more than 3 cts. per lb., and we have all we want to eat; but it is of excellent flavor. If we let it stay much longer the rains will wash it all away—bees, honey, and all.

M. S. ROOT.

San Diego, Cal., Oct. 26, 1886.

Thanks, brother Marsh. It must be the Root family take naturally to domestic animals, as it seems you have been getting acquainted with your horses and cattle, just as I have been getting acquainted with ours here in Ohio.—The information you give us in regard to the bee-caves is a valuable contribution to our knowledge. I presume the bees feel safe to take up with such a habitation, because you have so many months absolutely without rain. I suppose, that in your State one might start a big apiary, without very much of a cash outlay; that is, as fast as the swarms come off he could dig holes in the ground, and hive them, and so on, until the rainy season came. With such wonderful yields of honey as you occasionally have there, doubtless an enormous increase could be secured in a single season by securing a strain of bees much given to swarming; and who knows but that it is possible to cut a trench around the underground hives in such a way as to keep the rain from them, and thus have them winter over? A wooden bowl, or something of the kind, laid right above the brood-nest, would probably be all the protection needed, from frosts such as you have. You know I am very fond of having things cheap, and this idea promises cheapness, without any mistake.

BATH-TUBS.

FRIEND TERRY DISCUSSES AN IMPORTANT SUBJECT.

FRIEND ROOT:—In the best houses in the city, convenient bathing arrangements are quite common; in fact, they are the rule. But how is it in the country, among the rural population? It seems to be a general idea there, that a bath-tub is a luxury beyond their means, or, perhaps, they haven't thought much about it, but have gone along as their parents did before them. Or, possibly, they have wanted such conveniences, and didn't know just how to go to work to get them. Perhaps I can help some such persons a little by my experience, as I did friend Mattoon, of Atwater, O., by calling attention in GLEANINGS to our water-cart for receiving the kitchen-slops. Friend M., who has one, writes, "Am very much pleased with it. It is what we have needed for a long time."

When we were building our house, three years ago, we bought at a plumber's establishment in the city a copper bath-tub, 6 ft. long. They come all built in a nice pine box. In the city houses, the carpenter puts fancy work around this, at considerable expense. We did not care for this, but just set the box in the room over the kitchen, putting a narrow strip of wood around on top, and painting that and the outside of box. Then we got a common pump and some ½-inch and 1½-inch lead pipe. The pump was placed on a shelf on one side of the tub, and connected with the kitchen cistern with the ½-inch pipe. The 1½-inch pipe was used to carry the waste water from the tub down in the partition and out at the rear of the house. Then a little stove was put up to heat the room in cold weather. I do not remember exactly, but I think the entire cost was something less than $25.00 — possibly not over $20.00, and we have just as convenient a bathing arrangement as any farmer needs. Of course, he can spend $200.00 in fitting up a bathing-room, if he is able; but this is beyond the means of the masses. We have a large reservoir on our kitchen stove, and whenever there is a fire this furnishes hot water. It takes but a moment to dip out and carry up a pailful, and then pump in cold water to suit the feelings.

After bathing you have only to pull the plug out, and the water takes itself away. There is so little impurity in this water that we let it run off on the grass. During the heat of summer, nearly every member of the family uses that tub every night, the hired man as well as the rest. It gives good refreshing sleep, and, of course, better health, and keeps the bedding much cleaner. Working in the dirt is healthful and enjoyable, if one can clean up as soon as he is through, and slip on clean clothes for the evening and night. But how many workers in the soil do? My idea was to have it so handy that it would be almost no trouble to keep clean, and then it would be likely to be done. I never spent so small a sum that gave so great and continued satisfaction; and as copper and lead won't rust, it is there for life. Yes, we used to bathe after a fashion, occasionally (before we got the bath-tub) in a wash-tub or some smaller dish; but it was so much trouble getting the water ready, and carrying it out, that it didn't get done any too often, and it took away much of the enjoyment. And then the poor hired man! I suppose on many farms he has no chance to bathe, from one week's end to another. He is too bashful, perhaps, to ask for a tub and towel to take to the barn.

Not long since, a farmer who had gone to considerable expense to put up a windmill and tank, to furnish water for his cattle, complained to me that his cows didn't seem to like the water, for some reason. Like him, I couldn't see why, until I learned afterward that the hired man and employer's son were in the habit of getting a good bath in that tank, nights, after the folks were in bed! A hired man who works for one of the most respectable farmers in Ohio went home in July (began work in the spring), and went in bathing in a pond, and made the remark, "This is the first wash I have had this season!" Just think of that—going around with the filth of months accumulated on his body! And oftentimes the hired men are not the only ones who are in this fix, I am sorry to say.

Now, this is an unpleasant matter to write about; but there is a wrong here that ought to be corrected. Of all men, farmers most need frequent baths (and I take it bee-men are mostly farmers), and it may be safely said that they get the fewest. Just think: At a rough estimate there are over two million pores through which comes the insensible perspiration of the body. This makes some 27 miles of tubing. The matter that comes out of it is quite similar to the excretions of the kidneys. Stop this insensible perspiration entirely by an air-tight varnish, and the person must die. Stop it partly, with a thick coat of dirt and sweat and grime, and the health must suffer. First of all, should we fix convenient bathing arrangements on acount of the health of our children and men. I think Dr. Gunn once said, that filthiness is one great cause of rheumatism. Then it will pay in dollars and cents. A clean man sleeps better, feels better, and works better. I know, friend Root, that you would take pleasure in ordering a bath-tub for any reader of GLEANINGS, who needs one, and I do hope my few words may cause some not only to think about the matter, but to sit right down and send for one.

Hudson, O. T. B. TERRY.

Friend T., it seems a little singular that we have got just such a bath-tub for our new house as you have, and that our experience since using it has been so very much like yours. There is one point, however, you have not mentioned—the bath is a stimulant. Over and over again, when Saturday night has come I have declared I was too tired to move one foot after another, much less take a bath. "But," says my wife, "you know a bath will rest you. Time and again you have tried it." It is true; and when I get through I am ready to sit down and read my agricultural papers, and visit with the rest of the family, as if I had just got up in the morning. I never knew it to fail of making me feel rested and vigorous and strong. When a friend visits us, and we wish to have him enjoy fully all our home affords in the way of enjoyment, we ask him if he would not like to try our steam bath-tub, and words of praise follow at once; in fact, it is so much liked that sometimes one occupant follows another until the "machine" is kept going for quite a spell. I firmly believe that a man or woman will do more work, save money and doctors' bills, and live longer, by having such a bath-room as you describe, with every thing so handy that bathing is a pastime instead of something to dread. And, friend Terry, especially do I like what you have to say in the above paper in regard to the "hired man." May God help us to think of and plan for the above individual a little more, instead of finding so much fault with him! If he were provided with the conveniences such as you describe, and asked to avail himself of them, very likely we should find him more accommodating, more cheerful, and more inclined to look out for his master's interests. I will willingly correspond with the manufacturers of these tin-lined copper bath-tubs, and ascertain how low I can have them if I buy a number at a time for our bee-keeping friends. Ours cost $13.00.

ARTHUR'S BEES.

A Story for Boys.

BY MRS. CASTELLA WHITMAN.

ARTHUR was the eldest son of a farmer who lived in the southern part of one of the Northern States, a few miles from one of the towns that dot the surrounding country.

The origin of the following story has for its date July 4, 188–. As Arthur and his brothers had met with a great disappointment, their mother was anxious to make them as happy, and home as pleasant, as possible. Knowing that they were extremely fond of strawberry shortcake, and that a few yet remained, she suggested that, if they could pick them for her, she would make one for supper.

While thus engaged, one of them remarked that they must have disturbed a bumble-bees' nest, as the buzzing of *bees* attracted their attention. Scarcely were the words spoken, when it was evident whence the noise proceeded, for a swarm of bees was passing just over their heads. Arthur gave chase, and followed them nearly half a mile, across fields and over fences; then, coming in contact with a tree, they clustered on one of its lower branches.

Arthur's mother had been informed by one of the younger boys of what had transpired in the garden; and as he returned to her kitchen in so short a time, she supposed he had been obliged to abandon the pursuit; but as her eyes rested on his boyish face (which was usually pale, but now his cheeks were all aglow, with great drops of sweat on his forehead), she detected, before he recovered breath sufficient to tell her, that he had met with success.

Previous to the opening of our story, Arthur had often heard his mother propose to his father, that, even if he thought *he* could not handle bees, as it is termed, in any other way, he might have a large old-fashioned hive made, and keep it in some loft, so that they might at least have honey for their family; but no persuasion could convince him that he could take care of them in any form whatever.

Perhaps the reader will readily imagine that Arthur's mother had had some personal knowledge of them. Such was the case; and from her earliest rememberance until she was quite a child, her father kept them in the manner I have just alluded to, and she had often assisted him in his work. Fearing, however, that some accident *might* occur, she was very cautious not to over-urge.

To return to Arthur: After a short interview with his mother, he hastened to the field where his father was at work, and gave him a full account of what had happened, with an urgent request that he should assist in securing them. After much deliberation his father promised to see what could be done, much to the gratification of all. As supper time had arrived, the meal was hastily eaten, without any reference to the day.

By this time Arthur had become more composed, and thought best to go back to the spot where he had left his bees, to see if they were really there, and were as he had represented, while his father should find something in which to hive them. Nothing seemed available for immediate use, except a salt-barrel, which was soon sawed in two and made ready.

Arthur's quick return was sufficient proof that his bees were still there; and as soon as they were as well equipped for such an emergency as could be expected, they left the house, with the precautions of the family still ringing in their ears.

Success attended their efforts; and Arthur, upon their return home gave his father many compliments (in his boyish way) for his courage. "Why," he said, "father even drew off his gloves, and actually scraped the bees from the would-be hive, as, in their haste, after they once commenced entering it, many crawled up the sides."

The next thing to be done was to select a place suitable for them. Finally it was decided to place them under a large apple-tree in the rear and a little to one side of the house. As nothing more could be done until dark, each one took his accustomed place at the chores, which at least every farmer-boy knows better of what they consist than I have room here to describe. In due time father and son had the satisfaction of seeing the bees placed in their assigned quarters. That night, as Arthur and his brothers were reviewing the day, they thought they had enjoyed it as much after all as if they had been permitted to attend what entertainments the town afforded. Their mother here remarked, "My boys, you will seldom regret it if you willingly obey that which your parents think is for your good."

Continued Dec. 15.

LETTER FROM ONE OF OUR LADY BEE-KEEPERS.

WRITTEN FOR THE INDIANAPOLIS CONVENTION, BUT NOT USED FOR WANT OF TIME.

THE following letter was forwarded us through the kindness of Mrs. Robbins. You will notice the article was written to be read at the convention, and not to be published in GLEANINGS, which fact may induce our friends to overlook the exceedingly kind words addressed to the editor of GLEANINGS:

Mrs. Cassandra Robbins: Dear Madam:—The evening that GLEANINGS of Sept. 15 came, among other things of interest I read the extended notice and programme of the N. A. B. K. Society, and again I was seized with a desire to accept your kind invitation to attend the convention, and behold the faces, and sit at the feet, and learn of my numerous acquaintances which I have gained through the medium of the *American Bee Journal* and GLEANINGS.

But in that programme I did not find a certain thing mentioned for consideration in which I should suppose all *Western* bee-keepers would take unbounded interest; viz., manufactured comb honey.

Two or three years ago I met an elderly gentleman from Kansas, who, knowing I was an apiarist, informed me that people "out west" *made* honey, comb and all, by machinery. I "disdoubted" his statement, as the boy said, but failed to convince him of his error, and you will pardon me if I could not help smiling while he was talking. It was probably constitutional with him, so we must be charitable, knowing that—

"Men are preverse and oncertain creeters,
  And forget that 'tain't likely to happen,
 Their own private fancies
  Can always be cappen!"

Now, to take the aforesaid industry a little nearer home:

In the *American Bee Journal* of Jan. 13, 1886, we read: "I went to one grocer in this city who had recently purchased from *Ohio*, 1000 lbs. of what he honestly supposed to be real honey, and convinced him in five minutes that almost the entire quantity was made up of syrup, deftly secured in comb. He simply said, 'What are we coming to?'"

"Who is here so base that would be a bondman? If any, speak; for him have I offended. I pause for a reply."

Mrs. Robbins, you are quite right, I believe, in entertaining the idea that women are well adapted to the pursuit of bee culture. Our brothers are often a great help to us in this as in other callings, and, withal, so self-sacrificing.

One day last July my little seven-year-old niece, Florence, was visiting here. A short time previous she had been in the honey-house of a bee-keeper not forty miles from here, who had recently obtained a new machine in place of his old inferior and perhaps slightly disabled one, which worked *admirably;* and, what do you think? Out of the exceeding generosity of his great heart he told Florence that that old machine would be just the one for her aunt Marcia. Of course, my heart went out in gratitude for his thoughtfulness in my (?) behalf; but I was unable to see why *I* should not invest *my* money in a good machine as well as he; and up to this date the question stands open in my mind. But such disinterested solicitude should not go unrewarded.

Now, I am free to admit that I have a sort of admiration for bee-keepers as a class—men and women. I might name several of them, except for my extreme bashfulness. But I will not refrain from speaking words of commendation for our estimable friend, one of our fathers in apiculture—Mr. A. I. Root.

I have never had the pleasure of seeing him; but how could I help knowing him, after having seen so many interesting places and things through his pen—Mr. W. W. Rawson's cucumber-greenhouses and hot-beds at Arlington, Mass., for instance. Why, I almost wanted to begin work at once in a greenhouse and garden of my own. And then I should like to shake hands with him on the tobacco question, for I, too, *hate* that weed. I wonder how it is that he succeeds in helping so many to discontinue its use. It can not be simply the gift of a smoker, for that, in these *chronic* cases, would not serve as a *least inducement.* But, above all, he seems to be a man who lives his religion every day, and his articles and little suggestions are so helpful to us all who would know the better way, seek peace, and love righteousness.

And now, in conclusion, allow me to briefly congratulate all who have the pleasue of attending your convention. May each be socially benefited, and receive and impart largely of information. I hope you will not be denied the presence of any "quantity" of patent-right men, with their various wares—every one of whom has the best in the market; for what is a bee-keepers' convention without *them!*

Very cordially your bee-sister,
Shoreham, Vt. MARCIA A. DOUGLASS.

I am very glad, my good friend, to know that you are interested in cucumber greenhouses. I have oftentimes wondered whether the readers of GLEANINGS were interested in following me through this (to me) wonderful, and, in some respects, unexplored region of vegetable life as well as insect-life. I do think a small greenhouse would be next to a piano or organ for every home; and I do not believe it would be money wasted either, especially if the women-folks had enthusiasm enough to keep it neat and tidy. Blue Eyes is just now on a big tease for a little greenhouse. She can hardly think of any thing else, and she and her papa bid fair to revive the pleasant relations that existed between them eleven or twelve years ago. You see, she is now almost fourteen years old. I had hoped she might become a bee-keeper; but if her taste should run to floriculture instead, I will try to be content.—By the way, my good friend, are you not a little uncharitable toward that brother who offered to sell you his old extractor? May be he thought that, with your comparatively limited number of colonies, it would answer just as well as a new one, and would cost you very much less money.—I am much obliged for your very kind words. The tobacco business is God's work, not mine. I am very thankful that I have been worthy of being used as an instrument in his hands.

"HONEY IN TOO MUCH STYLE."

MRS. CHADDOCK ALSO GIVES US A SENSIBLE TALK UPON THE BEST GIRL.

I WONDER if we are not getting our honey up in too much style. Style is all right for rich people who are able to afford it; but it seems to me that, when we get our honey into pound packages, and then sell it to people who are too poor to eat on a table-cloth, and who care nothing whatever for style, we are making them pay for something that they do not want.

Two or three weeks ago I sold a man a box of honey. I drove up to his grocery and gave him the box, and told him I would come back after I had tied up the team, and attend to it. I did not get back quite as soon as I expected, and when I did I heard the conversation in the next room. The man said, "May be she won't want you to cut it out."

"I don't care what she wants," said the woman; "we buy the honey, and pay for it. We can't eat the boards, and we're not going to pay for them. If we have got to eat boards for a living, we can go to the lumber-yard and get some cheaper than these."

Here I went in, hoping to stop the desecration if possible; but it was too late. I had been very careful to get that nice honey all into good shape, rejecting, as I prepared it for market, all the sections that were not entirely sealed over, and leaving out all in which a single cell was broken; and, after all, to have it cut out and broken out and punched out, with great big thumbs and fingers, and dumped into a big bucket to settle down and all run into each other, just to save paying for the sections, was a little too much. I sustained myself as well as I could by repeating over to myself, "Cast not your pearls before swine," and, "He that is filthy, let him be filthy still," and other scriptural injunctions, but all would not do—*I was mad*—not altogether from the money that the sections would bring, but the wooden-headedness of it all. But I only said I'd know what kind of honey to bring them in the future, and I'd cut it out at home and bring it in in a bucket, and not have the honey dripping all over town. Since then two different parties have come here for honey, and they both asked if I would not cut the honey out, as the sections would be of no use to them. Just then I thought of something, and said yes, I'd just as soon cut it out as not; and I went to one of those 60-lb. hives of drone-comb honey that I got when *I wasn't* following Mr. Hutchinson's method, and *cut out* all they wanted, charging them just the same as if I had sold them the 1-lb. sections. Then I thought the matter over, and I have come to the conclusion that, for a certain class of customers, our honey is *too* fine, and next year I'm going to have *considerable* of that *big drone-sheet honey*, and I'm going to sell it to all the people who don't want to pay for "the boards." I'll give them their choice, and charge them the same price. May be if I were as poor as some of these folks who object to "the boards" I'd feel just as they do. There's a great deal of human nature in folks anyway.

MRS. CHADDOCK'S LOW PRICE OF HONEY.

When I told in GLEANINGS what I was selling honey for I little knew what trouble I was bringing on myself. First, I am scolded. Then people begin to send to me for honey, and I have to write and tell them that I have no honey to ship; I have no honey to *sell*. I have some honey on hand; and when people are sick, or have a wedding, and come to me for honey, I always let them have a little. Now, friends, kind friends, dear friends, don't any of you send to me for honey. I might write to all of you, and explain how it is; but I am almost always out of stamps; sometimes I have letters to send away, and have to wait two whole weeks till the hens lay enough eggs to buy the stamps with. Of course, friendly letters, and complimentary letters, are pleasant things to get, although from strangers; but nobody seems strange to me; and if you are willing to wait on the hens I'll answer them all. But when I get a letter wanting honey, that *sounds* like business, and I feel bound to answer it. I mentioned the price I was selling honey at, in one of the papers that I write for under a *nom de plume*, and I received a note that had been sent to the editor, asking him as a great favor to tell him who that woman was. I thought, now here is an editor who admires my style, and wants to hire me to write for his paper, and may be he'll pay me a hundred dollars a year; and I sat down and wrote him an awful sweet letter, telling him who I was; and then he wrote that what he wanted was to buy some honey of me. I felt blank, and answered him rather shortly, I am afraid. So, dear friends, I like you all; but poverty prevents my saying so in letters.

THE BEST GIRL.

I read last week, in Harper's *Bazar*, a *lament* by the editor. She says that our best young men don't marry *our best girls*. She says that the poor young men of the present are the rich and influential men of the future, and that is true; but that these same poor young men don't marry the *best* girls is *not* true. She says the reason that the poor young men don't marry the rich young women, whom she calls the *best* girls, is because the poor young men can not afford to buy the ten-dollar bouquets that custom demands him to give his partner at a ball; therefore he stays away, and the *best* girls have to hunt up somebody else. I know very little about society in New York. I've had very few ten-dollar bouquets presented to me; but I *know* that the *best* girls are not the society belles of New York or any other city. The *best* girls comprise the army of school-teachers who, about the middle of September or the first of October, begin their work in colleges, graded schools, and little red schoolhouses all over the United States. The *best* girls are in that other army of clerks in all the stores of the country and city. The *best* girls go in hundreds to work in our factories, dress-making establishments, printing-offices, and in the service of the Government. The *best* girls out in Dakota do housework, and get from sixteen to twenty-four dollars a month, besides their board. The *best* girls are the *working* girls who don't want a ten-dollar bouquet; and *they* marry our best young men.

MAHALA B. CHADDOCK.

Vermont, Ill.

Mrs. C., you may remember that I have written at different times about what we call "chunk honey;" that is, when we have honey that we can not get into good shape any other way, we cut it out into tin pans or basins, so much in a pan, and it has always gone off pretty quickly, at about two or three cents less than our comb honey in sections. You remember that friend Chapman (of the Chapman honey-plant celebrity) has always sold his honey in the same way. He puts a dollar's worth in a pan, and sells it, pan and all, for a dollar.—I agree with your closing remarks in regard to the "best girls." If there are any better girls in the world than those we have in our establishment, there is an encouraging future before the world just now; and I believe that it is pretty generally agreed that the girls who belong to "Root's factory," for general worth and intelligence, are welcomed in any society in or round about Medina. They are foremost in all good enterprises; they are conversant with the current literature of the day; they not only attend our best lectures, but they are able to follow our brightest and best thinkers; they are foremost in our prayer-meetings, churches, and Sunday-schools, and they are able and willing and ready to take hold of the great problems of the day.

SHADING HIVES IN WINTER.

FRIEND DOOLITTLE'S VIEWS ON THE SUBJECT.

A CORRESPONDENT wishes to know if it will do any good to shade hives, by way of preventing bees from coming out and dying on the snow. To which I reply, Yes; and I would also say that a shade of the right kind is very beneficial in other ways. Some seem to think that the sun does not warm up the interior of a hive to any extent so as to disturb a healthy colony of bees; but from years of experience I am convinced that such are mistaken. Even chaff hives are warmed clear through their thick walls so as to make the bees break their cluster and run about the south side of the hive, along the warm material, to such an extent that it often results in disease. Especially is this true if the hive is painted any color other than white; for the darker the color, the more heat there is absorbed. I have repeatedly looked into hives at about 3 P. M., on days when the sun had been shining brightly; and although the mercury then stood below the freezing-point in the shade, the bees were lively and active across the whole length of the front, or south side of the hive, while the north side of the interior of the hive had no bees about it, and that side of the cluster was unbroken. Besides this, many bees would come to the entrance, and, finding it warm and nice there in the bright sunshine, out of the wind, would take wing, only to be chilled as soon as they left that comfortable nook, made so nice by the warm rays of the sun. As night came on, the cluster was again formed, only to be broken the next day, and so on, until disease was contracted, or the colony materially injured from the loss of bees.

After watching proceedings for some time I began experimenting by shading the front of a part of the hives, while others were left as before. All those shaded were found quiet, with an unbroken cluster, at 3 P. M., while those not shaded continued to parade along the south side of the interior of the hive, and fly out and get lost. I now shaded all of the hives, since which I have been far more successful in wintering. For a shade I use a board about one inch shorter than the front side of the hive (hives face south), and a little wider than the hive is deep. This board is set on the bottom-board of the hive or the alighting-board, out about six inches from the hive, when the top is leaned over against the front of the hive. In this way there is an average space of three inches all along the front of the hive, so that a free circulation of air is allowed, thus keeping the front of the hive as cool as the back side. When snow falls, the entrance is not clogged with it, and it also keeps strong winds from disturbing the cluster and cooling the interior of the hive by blowing in at the entrance. Again, it allows all the old bees to come out of the hive to die, as they always will do if they can, so that the entrance is not so liable to get clogged with dead bees. When it is really warm enough for bees to fly, this board is no hindrance to them, but, on the contrary, it keeps the entrance in such a condition that they can fly at any time when it is warm enough, without any assistance from the apiarist by way of shoveling snow, etc. In the summer these boards are left turned down right in front of the hive, so as to give a large even surface for the bees to alight upon, as well as to help in keeping weeds and grass down. I am so well pleased with them that I could not think now of getting along without them. As they will soon be needed, I give this in time so all can try a few and see whether I am correct in my conclusion or not.

G. M. DOOLITTLE.

Borodino, N. Y.

Friend D., I at one time thought a good deal as you do; but I have so many times had, as I thought, abundant reason to think that hives that stood in the sun did much better than those that were on the north side of the building, I concluded the sun was a decided advantage in the end. Shading only the *front* of the hive in the way you suggest, may make quite a difference, however. But, don't these broad shading-boards warp up so as to get unsightly, when one side is against the ground, and the other right under the blazing sun of summer? I know such a board keeps down weeds, but it makes such a lurking-place for spiders, toads, and other vermin, that we have several times rejected them. May be you clamp your shade-boards to prevent warping; and if so, we should be glad to know just how you do it. We have never found the sun a a detriment in our locality.

THE SOLAR WAX-EXTRACTOR.

ALSO SOMETHING ABOUT THE USE OF KEROSENE FOR LIGHTING FIRES.

DEAR MR. EDITOR:—I promised last summer to report, at the end of the season, as to the value of the solar wax-extractor which you so kindly donated to our college. We like it so well that hereafter we shall use no others, except in a very limited way, just to show our students how they work. First, this extractor is so convenient. It is ever ready, and we have only to throw in our old combs, fragments, or cappings, when, in a few hours, we have them all rendered into the very nicest wax—no firing up, no possible litter or muss, all clean and fresh, out in the pure air, where room is unstinted.

Again, there is no danger of overheating and injuring the wax. Without the least watching or care, we are sure of the very nicest of wax.

We find it best to add only enough comb for one day's rendering. This gives us better results than to fill up the extractors, as in this way we get the wax very clean and nice.

I have learned one little lesson from this wax-extractor experience. That is, when a man of the ability, candor, and experience of O. O. Poppleton recommends an instrument, practice, or system, it is no part of wisdom to let the advice pass as an idle tale. We ought to have had a solar wax-extractor years ago.

It may be said, "Yes, wax-extractors are a good thing for one with a few colonies of bees; but they are not the thing for the 'big guns.'" I do not see the force of this. If they are desirable at all, I think they are for all. We can enlarge or multiply the number of extractors, and thus secure the same advantages in a large apiary that the solar extractor gives in a small bee-yard.

It seems to me that the style you sent leaves little to be desired—a plain tin-lined box with two hinged covers, one a glass one, the other wooden, lined with either a tin reflector or a glass mirror. I would add a couple of iron strips, one at each end, so that the upper cover could be held in just the position desired.

KEROSENE OIL.

I am glad you have told the readers of GLEANINGS how to light their smokers. The little oil-can is safe, and its use saves much valuable time. Knowing your desire to aid your readers in every way, I wish to add a word as to the use of kerosene oil. You know many use it to light the fires, especially in the kitchen stoves. I have seen several parties turn kerosene right from the oil-can into a stove, and in two cases there was abundant living coals in the stove at the time, as shown by examination made upon the spot.

Our children were much amused the other day in reading in their *Youth's Companion* of a man who "swore a terrible oath; he said, 'By hemlock.'" I am sure such terrible swearing would almost be warranted by the sight of such a criminally careless use of kerosene. I say *criminally* careless, and I mean it. It is a crime to thus endanger life and property. In our own State there have been several funerals in consequence of just this reckless use of kerosene. It is certain that no one ever has a right to induge in so foolhardy a practice.

I wish now to give a modification of this method, which is entirely safe, and which we find exceedingly convenient. We roll up a small roll of cotton cloth, about as large as a small orange, and saturate this with kerosene. It is not necessary to add so much oil as to cause the rolls to drip, or to be unpleasant to handle. These are kept in a safe place, in a close tin can; and as a dozen or so are made at once, they are always ready for use. One of these, laid in a stove, and covered with the usual stovewood, placed as required to make a good fire, and the ball then ignited, will give us a good fire in an astonishingly quick time. We value these kerosene balls very highly. A. J. COOK.

Agricultural College, Mich.

Friend Cook, I knew, when Mr. Poppleton first told about the possibilities of the solar wax-extractor, that they ought to be offered for sale, and introduced generally; but with the many burdens on my time and brain I felt obliged to let it pass by, and so it went until it was revived by somebody else.—I heartily indorse your remarks in regard to kindling fires with kerosene. The plan you suggest is now in use in many families; and a still cheaper absorbent of the oil than a ball of rags is corn-cobs cut up into pieces two inches long. Put these in a pail or stone jar, and pour on your kerosene. After they have absorbed all they will, pour off the residue and they will never drip. I believe there was at one time a patent on a piece of pumice-stone fastened to the end of a piece of wire. This is dipped in a vessel of oil kept at some distance from the kitchen stove. After the fire is lighted, the stone is removed by the wire handle, and can be used over and over again. One of the advertisers in GLEANINGS uses a little ball made of old newspapers.

SELLING BEES AT PUBLIC AUCTION.

SOME SUGGESTIONS IN REGARD TO MANAGING SUCH A SALE.

I HAD determined to reduce the number of my colonies, and also sell most of the stock on the farm, in order to devote more time to the ministry. It became a matter of considerable anxiety as to whether the bees would sell for what they were worth, being late in the fall (19th of Oct.), when I was to have a sale. Of course, the surplus honey was all removed, and the crates and supers all packed away into the honey-house. The apiary wore a kind of deserted appearance, as is usual when the season's operations are over. I stated, in the sale-bills, that the hives would all be carefully and plainly numbered, and the purchaser's name placed on the hive, and that I would winter the bees, and guarantee them in good condition the 15th of April, 1887. I also went over the apiary before the sale, and carefully graded them—No. 1, No. 2, Italians; and No. 3, hybrids.

The day of sale proved to be very fine and sunny, and we had a large attendance. When we finally came to the bees the bids ran up to $5.00 per colony for the best, and all the No. 1 were taken at that price. Then the No. 2 ran up $4.50 per colony, and all of No. 2 were taken at that price.

The bidding was more tardy and lifeless on hybrids, but finally $3.50 was reached, and quite a number were taken at that figure. But I concluded not to urge the sale of them at that figure, and so I have left on hand some 50 colonies, which I will keep and Italianize next season.

The situation of the bee-keeper has been somewhat discouraging the past season, owing to the depression of the market for honey. A great many farmers saved their bees over last winter, and nearly all have more or less, and quite a good many had a surplus, and put it on the home market at a low price, on account of its being in bad shape.

I forgot to state that my terms of sale were 12 months without interest, and also that purchasers bought only the lower story of hives, with the option of taking the surplus arrangements in the spring, at the regular price. The prices may seem low to many of my brother bee-keepers; but then, they were *all* disposed of in an hour; and considering the low price of all classes of produce, I don't know but the bees sold for enough—at least, I feel pretty well satisfied. I am at present located (for three or four weeks) in the northwest corner of Iowa, holding a series of meetings. It was only a few miles from here where, a short time ago, the Rev. Geo. Haddock was so cruelly murdered for his having taken an active part in seeing that our prohibition law is carried out. The effect of the assassination of this minister is to unite temperance workers. Quite a number have expressed to me here, that they have, only since they have witnessed this cruel murder, had their eyes opened to the real wickedness of the rum power.

This is a beautiful country—rather too new for bees to do well, being mostly fresh prairie lands —not much white clover nor other honey-plants.

D. E. BRUBAKER.

Marcus, Cherokee Co., Ia., Oct. 30, 1886.

BACTERIA.

FRIEND COOK THROWS SOME LIGHT ON THE SUBJECT OF REMEDIES FOR FOUL BROOD.

I THINK readers of GLEANINGS will be interested in some experiments that have just been carried on in our laboratory by one of my students. It may not be known by all that all putrefaction, or decay, of organic substances of animal origin is due to the development of minute vegetable organisms, or so-called "bacteria." These tiny plants scatter their still tinier seeds, or spores, as they are called, which, as mere specks, not visible at all except when highly magnified, are borne everywhere by the air-currents, and so are ever ready to fall upon any inviting soil, where they may germinate. The *Bacterium termo*, which looks like two links of a chain, finds the requisite soil and conditions in dead animal tissues, and so is ever ready to seize upon them. If the moisture and heat are sufficient, growth and development take place, the dead tissue is consumed, the bacteria grow apace, and, as a result of the changes, foul gases are given off, which quickly convey to us, if we approach the seat of the phenomena, the exact state of the case. Foul brood is much the same, only there the fungoid growths are able to fasten on to living organisms instead of dead tissue. All organic matter is susceptible to such attacks. Putrid or decaying milk suffers in the same way. T. Landon Sanderson, a distinguished English scientist, has just shown that milk is often rendered very injurious to infants if bottles are used that have rubber nipples, especially if long rubber tubes are used. Bacteria develops in the milk left in the tube; these are carried to the stomach of the babe, and often continue to swarm and multiply in the alimentary canal, and so injure if not victimize the helpless infant. Thus it is seen that only such apparatus should be used in such cases as can be thoroughly and perfectly cleansed each time after use.

Seeing the statement in the *British Bee Journal*, that not only carbolic acid and salicylic acid, but also coffee, would destroy bacteria, I asked one of my students to test the matter. The following is the result:

Ripe tomatoes were placed in water, and slightly boiled. This decoction was then placed in several tubes. In one phenol was placed; in another, salicylic acid; in another, a strong decoction of coffee, while a fourth was left exposed with no fungicide added. In four days the last two tubes were clouded, while the other two remained clear. Examination, with a 600-power microscope showed that the clouded liquids were the scene of extensive fungoid operations. Bacteria of several forms were rolling and pushing and scrambling by and over each other, reminding one of a pond full of most active wrigglers, or polliwogs. This is a most wonderful sight. We take no more water than the smallest drop, and place this between two glasses, placed flat, the one on the other, and yet, wonderful to relate, we see millions of these little wrigglers sailing about as though the world were before them, so small are these minute fungi. Similar examination showed that the clear liquid had no such miniature life. Thus, while carbolic acid and salicylic acid will prevent the development of these minute fungi, coffee did not seem to do so.

Some of the cloudy liquid was then placed in each of these tubes, to which was added carbolic acid, salicylic acid, and strong coffee, respectively. In a few hours the odor and life had all disappeared from the two first tubes, while in the tube with coffee the life and odor were still present. Thus we conclude that coffee is worth more to nourish our bodies and tickle our palates than to destroy foul brood or other bacteria. A. J. COOK.

Agricultural College, Mich., Oct. 30, 1886.

We are very glad indeed, friend C., to hear of these experiments; and while they do not indicate positively that carbolic acid and salicylic acid are antidotes for foul brood, it very much strengthens the idea. I have all along felt that the suggestions thrown out, that coffee might prove a remedy for foul brood, was a mistake, and I am glad that you have shown by actual experiment that it has no effect one way or the other on bacteria. Now, are we to understand that an infusion of tomatoes, such as you made, will, after being exposed to a warm temperature three or four days, always give birth to these same forms of bacteria? If so, I suppose the explanation would be that the spores of these lower forms of life are always floating about in the atmosphere. If this is so, we are forced to conclude that the frosts of winter have no effect in destroying the life of these spores, and I believe this is true in regard to real foul brood. A heat equal to boiling water, however, if I am correct, destroys all insect and vegetable life. Boiling water is, therefore, the only safe means of rendering hives and utensils, that have been in contact with foul brood, harmless for future use. I presume we are to understand from your remarks, that *phenol* and *carbolic acid* are virtually one and the same thing—at least, you seem to use the terms indiscriminately.

I would place the use of common salt, as a remedy for foul brood, in the same category with coffee. It has been suggested, that foul brood is caused by lack of common salt. Now, this is surely not so in our case, for we have been in the habit for years of killing weeds in front of the entrances of the hives with salt; and perhaps two or three barrels have been used for the purpose. Every time we have a light shower, the bees have salt water to their hearts' content, right before their noses. Shall we not let reason take the place of using drugs in the dark, in the hope that we may possibly blunder on something that will hit the spot?

FRIEND GOULD'S SECTIONS.

J. B. MASON GIVES HIS OPINION OF THEM.

IN looking over GLEANINGS of Nov. 1, page 858, I find a description and also an illustration of the Hutchins box, as described by Ralph E. Gould. In these new things that are coming up daily, we want to learn all their good points, also all their bad points; and this is what our journals are for, that we may communicate with each other and thereby save others the expense of going over the same ground to try things that have been tested and found faulty. GLEANINGS has saved me hundreds of dollars in this way. If GLEANINGS cost $25.00 per year I should consider it the best investment I could put $25.00 to, and here are some who can't afford to pay $1.00 for it, or, at least, they think they can't. Well, all I can say is, it is poor judgment on their part. But, to return to the Hutchins box.

In justice to friend Gould I will say I have never used this style of section, so due allowance should be made in any thing I may say of the box. Possibly I might like it better after using it.

At our State Fair was the first time I ever saw the box filled with honey. Friend Gould had quite a large display of honey in this style of section, on exhibit and to sell; also one case holding these boxes, that had been on the hive, and filled, or partially filled. This honey was placed alongside of my exhibit. We were allowed to sell honey at wholesale and by the box, also by the plate. And right here I owe you thanks, friend Root, if not money, for the description of how you sold honey at the fair. I tried it, and it proved a perfect success. Friend Gould was away most of the time, and I looked after his exhibit. He gave me liberty, if I came short, to sell from his. I offered some of his to those purchasing a box, to carry away; but I found, first, that people wanted to see that hidden side; second, that, in removing the cover as carefully as one could without extra care, the section was so frail that it would twist enough to crack the cappings of the honey and set it to leaking; third, that the shape of the box with the cover on is such that it is naturally carried on its side, and that the honey was badly broken. I found that people chose the open section, and had it done up in a paper, at the same price, feeling that they were getting more for their money, although that might have been partially the light weight, as I found these sections did not contain nearly a pound. Judging from the feeling, I can hardly see how those sections bring readily 2 cts. per pound more, as friend G. says. The case on exhibition was not very attractive, as it was. These boxes were so thoroughly cemented together with propolis that it looked to be quite an undertaking to get out the boxes and clean them. Friend Gould says that separators cost $1.50 per 100. He obtains with the box nothing but wood separators, which can be obtained for 75 cts. per hundred. Then he speaks of the boxes coming all put together, as though this were an advantage, which I should consider a decided objection on account of their bulk. It might do for one who lived near the manufacturer, as friend Gould does; and as for shipping honey, no device that conceals the honey entirely from sight is practicable. I received a lot of comb honey from one of our leading honey-merchants last year, in which the honey was packed in a box entirely from view, and might have been taken for a box of iron or stone, and it got such usage that it was entirely smashed up. Now, if this honey had been shown by glass at the sides it would not have been thrown around by the railroad men as it was.

Mechanic Falls, Me. J. B. MASON.

I am very much obliged to you, friend M., not only for the kind words you give us in the outset, but for the report you make in regard to the practical working of Gould's system of getting comb honey. I did think of the light section, but forgot to mention it. Of course, they could be manufactured of heavier material, without probably increasing the expense very much. I also omitted to note the excessive freight charges that purchasers would have to pay on boxes set up. Notwithstanding this, however, we send out a good many sections folded up, with starters put in. We had a little experience some time ago in receiving honey by rail, that was boxed up tight so no one could get a glimpse of the contents. It turned out about as you mention.

BUZZING AND HUMMING.

HOW DO BEES UTTER AUDIBLE SOUNDS?

AS there is some interest just now as to the sounds made by bees, it may not be out of place to quote from Frank Cheshire's excellent book. On page 149, Vol. I., he says: "It would be extremely erroneous to conclude that the wings alone, or even mainly, give out a note." "Landois recognized three tones in the flight sound. The first produced by the wing-beats; the second, sharper in character, by the vibrations of the abdominal wings; the third, the most acute and intense, from the action of the true vocal apparatus, placed in the stigmatic orifices." He says the wings undoubtedly do the buzzing, but the humming is as clearly the outcome of a special apparatus connected with the breathing-tubes, and that this humming, which may not inaptly be called the bee's voice, is caused by muscular contractions within the thorax, these contractions being the same that cause the wings to vibrate. This may sufficiently account for the tremulous motion of the wings spoken of by G. M. Doolittle (GLEANINGS, p. 855), without attributing it to the tremor of the body. Indeed, when the queen is piping, no movement of the body can be seen, as I certainly think would be the case if the tremor of the body were sufficient to cause such plainly visible motions of the wings.

PACKING BEES IN LONG BOXES.

On page 849, Arthur W. Jewett tells about packing hives in long boxes, letting the bees have winter flights from these, and then taking out the hives in spring, and setting them on the summer stands. Among my dreams of plans for wintering without hauling home my bees to put in cellar, is one which consists in having a long box, or hive, chaff hive if you please, say ten feet long, and thus having a capacity of perhaps 80 combs. In one end of this would be put a colony of bees on 4 or 5 combs, having abundance of stores, then a bee-tight division-board made of ⅜-inch boards, then another colony, and so on. This would allow 12 or 15 colonies to be packed in a length of 10 feet, and the box or hive might be made double, having a central board running the whole 10 feet, and serving as the back for each hive. Thus there would be great economy of heat, each colony helping to keep its neighbor warm; but a serious practical objection in my mind has always been that these colonies could not be moved in spring or early summer without flying back to their old location. As Mr. Jewett has had practical experience on this very point, I should like to ask him what has been his experience. Is there no loss of bees from flying back when the hives are moved in the spring? and if so, what is done to prevent it?

DOES CELLARING LESSEN THE VIGOR OF BEES?

I have heard some claim, that, of two colonies, wintered the one on its summer stand and the other in the cellar, exactly alike in the fall, the cellar bees would be more tender in the spring from lack of exposure, and, as a consequence, would build up more slowly than the others. If there is any truth in this, it ought to be taken into account in comparing the two methods of wintering. If Ernest should conclude to cellar some colonies, I wish he would especially notice as to this point in spring.

SALT FOR BEES.

Until this year I never tried giving salt to bees. During the past summer, however, I found in the bees' drinking-pail "wigglers," or mosquitos, in the larval state. To prevent this I threw a good quantity of salt in the water. The bees worked away at the water, and some of them worked directly on the piles of wet salt, which, lying on pieces of wood, had not yet dissolved. To find out whether any of them were after salt more than clear water, I put a pail of clear water beside the salt water. Scarcely any bees worked on the fresh water; but bees are always slow to commence on a new place, so I made the fresh and salt water change places, and in a little while the salt water appeared to be the favorite. I had never before thought that bees need salt; but where there is an eagerness to obtain something, it is pretty good evidence that they need it. I am aware that every now and then some one raises the cry that salt is injurious, especially to the human family; and while I believe that, like almost every thing else, an excess may be injurious, a certain amount is required. I accept as a literal truth, the words of our Savior, "Salt is good." C. C. MILLER.

Marengo, Ill., Nov. 3, 1886.

Friend M., the idea of packing bees in long boxes has been tested pretty thoroughly; and one of the obstacles in the way, if not the *great* obstacle, is loss of bees by changing their location, both when they are put in this long box, and when they are taken out and put in regular hives. If the bees were carried three or four miles, however, when putting them in and taking them out, I think this trouble would be perfectly remedied. You would, however, be obliged to have the bees and combs in a movable case that could be lifted out of your long box, and carried to its destination before they are allowed to fly. I am inclined to think it will be found almost too much machinery.—When I practiced cellar wintering, and compared it with outdoor wintering, I was inclined to think the colonies wintered outdoors were, as a rule, in the best condition, when ready for honey-gathering.—Many thanks for you clear and satisfying experiment, to prove that bees prefer salt water to pure water. Now, I should like to know if you made any experiments to see just how much salt had better be used—say to a pailful of water. I, too, believe that salt is good; and it seems to please our domestic animals so much that I would give it to them as I give them apples, even if I did not believe it to be conducive to their health.

WINTERING.

BROOD-REARING LATE IN THE FALL NOT ALWAYS A NECESSITY FOR SAFE WINTERING.

OUT of 77 colonies and 2 nuclei, my only loss last winter was three queens. I used the queens in the nuclei, and doubled the remaining colony with another. I have now 76.

The bees were wintered in a temporary cave, which, for the benefit of some, it may not be out of place to describe here.

I have no land of my own as yet, so I can not build a cellar with underground ventilator, etc., as I should like to do. I made my cave 3 feet below the surface, 10x16. Three upright posts were placed on each side, and three rafters were laid on top of these. The sides of the cave were the only support to the posts. Boards were laid around the outside, and banked up with straw and earth to the top. The roof was made by laying boards on the rafters, then 3 inches of chaff, and then another layer of boards, lapped, to keep out the rain. It was 6 ft. high inside, roof slanting one way; a door in the end, and two blind ventilators, completed the cave. I have used it successfully the last two winters, and would much prefer it to any cellar under a house, which is used for general storage—any thing except a cellar built expressly for bees. Old cellars usually have more or less foul air, while in this cave the air is pure, and it never reaches the freezing-point. I do not think the thermometer fell below 40°, any time last winter.

I can build such a cave in two days, by using new 16-ft. lumber; and it would surely pay any one, having thirty or more colonies, to build such a cave, if bees have no better place for winter quarters.

My bees are all in Gallup ten-frame hives. They were contracted to six and seven frames. I filled the space behind the division-board with chaff, and chaff covers, with four inches of loose chaff on top.

BROOD AND YOUNG BEES.

We read a great deal about colonies having plenty of brood and young bees previous to their going into winter quarters. With this I heartily agree; but I made some observations last fall that were not quite in accordance with it. The first week in September, 1885, was very cool, and the bees huddled close on the combs. Then the weather became very warm, and honey came in so fast that the brood-comb was filled as fast as the young bees hatched out. Extra combs were given, but it seemed as if honey were stored everywhere, and several of my best queens could not be induced to commence laying again. I reasoned that, if the queen stopped laying in the early fall, she would commence sooner in the spring (honey being plentiful and of good quality), and I think my reasoning correct; for when those hives were set out this spring they were full of bees, all had abundance of brood, and are among the best I have. Most of the hives hatched brood three and four weeks later, but were no better.

Some advocate having one or two empty combs in the center of the brood-nest, for clustering. I gave nine combs full of honey. The bees hung below and close to the entrance. I presume empty combs are beneficial when bees are wintered out of doors; but in the cellar I should not deem it necessary. ROLAND SHERBURNE.

Lone Tree, Johnson Co., Iowa.

Friend S., your wintering-cave is not unlike many that have been described before. The objections are, the general untidiness of such a temporary arrangement, and also that, during many winters, they do not seem to have kept the frost out sufficiently. Quite a number of the veterans have decided that they not only want a building above this repository, but they want a fire kept in that building. I believe you are a smarter man than most men whom we ordinarily come across, if you can build such a structure as you describe, and have it frost-proof, and do the work in two days; yet I know from my own experience how much even an ordinary man can accomplish when his heart is really in the work.

CATNIP TEA VERSUS HOT WATER.

A LETTER FROM DR. HIGBIE AGAIN, ON THE WHYS AND WHEREFORES IN THE USE OF MEDECINE.

HEALTH is one of the greatest blessings that a person can enjoy in this life, and a great many people enjoy it for a long term of years without knowing or caring whether it is preserved or not, and regard it as throwing money away to obtain information in that direction. Without health, the prospect of doing much good in the world is rather small, and it should be the duty of every one to study to live up to the conditions that will secure health. I think it wrong to teach that, because we have sickness in the world, it is not possible to avoid it. If God does allow sickness to come upon us, he has, on the other hand, given us reason and intelligence to prepare against and neutralize it. We have it in our power to investigate in such a thorough manner that it may be speedily removed when it comes, and also to avoid the conditions that are sure to produce it. The science and philosophy of prevention is much more valuable than the science and philosophy of cures. If people had the interest, and would make use of the means, and spend as much time to prevent sickness as they do to cure themselves when sickness exists, there would be much less suffering in the world, a large amount of valuable time saved for chosen pursuits, and a great many less doctors in the way, and fewer doctor-bills to pay.

Now, Brother Root, you have asked for more light on the subject of medicine, and, to make a point, you have asked a stupendous question: "Suppose I should drink a gallon of the strongest catnip tea that *could be made*, inside of 24 hours, would it do me any harm?" Now, first, let us look at the quantity; second, the conditions. The quantity would be 5⅓ ounces every hour, of the "strongest tea that could be made." The conditions would be twofold —first, on the side of the tea; second, on the part of the system. If the tea were taken warm it would have one effect; if hot, another; and if cold, still another. If taken warm, the effect would be nausea and sweating; if hot, such a terrible relaxation of the cutaneous vessels would follow, that the whole system would suffer: unless the cooling process were carefully guarded, I should have no desire to be the victim—the condition would be extremely dangerous; if taken cold, the effect would be tonic and stimulant. A woman could do two washings in one day under the influence of such tea, but she would not feel like washing her hands the next. I have known many women to drink an extra *strong* cup of tea on washing-day, and do no more work for a week. The philosophy of this process is plain. Over-stimulus incites to over-exertion, and both are injurious to health. You again ask, "Does not the warm drink do the work, many times, when the catnip has the credit?" I answer: If warm water possessed the properties needed to meet the conditions and wants of the system, that would be just the remedy; if it did not possess those properties, it would be no remedy at all, and valuable time would be lost. It is an admitted and well-known fact, that different substances possess different properties, and that different diseases demand different treatment. For a recent cold, a remedy that will open the pores and produce sweating is just *the remedy;* but who would think of using the same remedy for rheumatic or typhus fever, for inflammation of the eyes, or a sore toe? Now, when a fellow feels a "tremendous cold coming on," a rush for the stove, well fired up, is a rush in the right direction; and that "dipper of hot water with the feet in the oven" is a valuable remedy just at this time, and the circumstances *combine* to make quick work of that cold. The only unfortunate circumstance is, that the oven is only large enough to admit the feet. Now I am sure if some of that hot water in the dipper, say a pint, were turned upon half an ounce of dried catnip top, and used freely as the water, after steeping about three minutes, you would find a great improvement in the treatment, because the plant possesses properties that the water does not, and properties that are indicated strongly, and must be brought into use by employing some agent. I would not attempt to discard or lessen the use or benefit of water in its many modes of application, when directed by experience and good judgment; neither would I attempt to discard or lessen the value of any of the long-tried, well-tried, and successfully tried products of the vegetable kingdom. The majority of the best-known remedies in the world to-day are from the vegetable kingdom, and freely acknowledged as such by every medical school except the "Hydropathic." Water is the world's panacea in their estimation, and nowhere can any thing be found that is of equal value. Every pain can be stopped, every exalted condition can be reduced, and those too much reduced can be brought up to a healthy standard. Theory is beautiful, but practical benefits are more so. God has given us a beautiful vegetable world, and the value of their medical properties should be prized as highly as their external beauties, and the immense range of application where these properties may be employed to meet the wants of the human family are equally great as the range of the beautiful. Beauty is the value of the one, and healing and cleansing energy the value of the other. Beauty can rise no higher, for the zenith is reached. Philosophy and chemistry are luxuriant plants, and are rising to grander and more systematic proportions every day. N. L. HIGBIE.

Elsie, Mich.

Friend H., perhaps I was careless in saying a gallon in 24 hours. I simply meant, suppose I should drink *lots* of catnip tea. I admit, that you are right in one part of your reasoning; namely, that while a dipper of hot water would be an excellent thing for a *severe cold*, experience and common sense would indicate that it would have no effect whatever on a *sore toe*. If, however, instead of drinking the water, we dip the toe in it, I think it might have some effect. Very likely catnip has properties such as you suggest, and that it will hit the spot when such a remedy is needed, but produce no effect whatever when not needed. I believe in doctors, and we send for one occasionally; but I confess it is with a good deal the same feeling I should try to do something for a *severe* bee-sting. See my answer to G. A. Farrand, on page 903.

FOUL BROOD.

NOT CAUSED BY UNTIDINESS.

ALTHOUGH I have never had any foul brood since I have kept bees in this country, my eye (as a mattter of custom) is so suspicious that I should likely notice it as soon as opening such a hive, however little affected, or even outside. The reason is, that we were so much troubled with it the time I first learned how to work with bees. Some bee-keepers think that foul brood (if they believe in such a thing at all) is the consequence of untidiness about the hive; yes, some smart ones tell me that there is no need of getting such a thing. Such ones will find out, without need, where bee-keeping begins, as anybody in a good locality, and in a good season, can "milk the bees" with an extractor, and lose half in winter. This latter is not even necessary in a warm climate. I consider the last-named point of 100 times the importance of examining the bees before winter to see that every colony has a good queen, as even an expert can see that, very near to the entrance of his hives. Even suppose a colony would have no queen, it would be of little or no future consequence; whereas, if one colony had contracted foul brood, and it were overlooked in the spring also, the next season the whole apiary would likely be affected, and worse yet; his neighbors' also, and finally he would sell some of his honey far away for some one to feed his bees with, or rob it from some grocery-store. You see, friend Root, I think that every bee-keeper should know something about foul brood, as well as that every doctor should know something about cholera morbus. In your own case I think the most and least work you can do (as is the rule in many cases), is to do nothing, comparatively, as the season is, so to say, near with you, and not ship or sell any bees anyhow this season. I would only keep an eye on the affected and suspected ones, and examine such with customary care, and treat them; mark each, and keep them strictly separate. After all have gone out of brood, it is an easy matter to detect any affected ones, should there be any. It would be too much of a risk to open so many now, on account of robbing; for in hard times for bees they will often smell and try hard to enter hives the next day that have been opened the evening previous. The bees of any affected colony found in the fall can be shaken out from the combs; and, after a day's fasting in a box, put on a sufficient number of clean combs, and feed on good honey or sugar for winter.

I do not as yet take any stock in curing foul brood with acids; and even if it could be done, I consider it too laborious, without any apparent reward, especially since we have foundation; but I would put a few drops of acetic acid in the feed to prevent or expel bad odors from the hive, which is also a sure preventive for keeping sugar syrup from granulating. The odor is, or seems to be, very much liked by the bees, as well as by most men. I have always used it when I had to feed any sugar for winter. A slight scent of this agreeable odor will remain in the hive all winter.

Hammonton, N. J. C. H. LUTTGENS.

Friend L., I am glad you have called attention to the very serious consequences that may result from a little carelessness where foul brood is around. Prevention is surely better and easier than cure, especially where you contemplate curing a whole apiary or a whole neighborhood.

FRIEND TUTTLE'S PHOTOS OF PROMINENT BEE-MEN.

SOME CORRECTIONS IN REGARD TO OUR NOTICE.

I NOTICE in the last number of GLEANINGS your remarks on my new photograph of bee-keepers. While I thank you for some of the things you have said in its favor, I think you have done me an injustice by representing it to be essentially the same as yours. You say a *large proportion* of the pictures are the same as are in your medley, while, in fact, only 26 persons out of the 120 are in your medley at all, and 20 of these are copied from photos taken since your medley was made; so in reality there are only six in mine that are the same as they are in yours; namely, Kirtland, Wagner, Parsons, Grimm, Cary, and Gallup. I have been very careful to secure good portraits, and many of them were taken on purpose for me. I have also been careful to use only such as have become well known by reputation (one or two excepted). Instead of giving the size of my picture as 11x14, which it really is, you have measured the bare print, and called it 8½x11; while your picture, measured in the same way, would be 9x10½, instead of 11x14, as you advertise. E. O. TUTTLE.

Bristol, Vt., Nov. 9, 1886.

Friend T., I had no thought of doing anybody an injustice; but, of course, I did not take time to count up the names as you have done. In regard to the size, if you and I, both of us, have been giving the size of the cardboard on which the photograph is pasted, I think we had both better be straightened up, and I thank you for calling our attention to the error in our price list.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from Oct. 15.

CHAPTER XXVIII.

Wise men lay up knowledge.—PROV. 10: 14.

It is now November; and as many have inquired in regard to the workings of the New Agriculture during the past summer, I will go over the ground a little. In the first place, I have been much better pleased with its working on the low ground, inclined to wetness, than on the uplands and hillsides. Perhaps this is largely owing to the fact that the summer of 1886 has been an exceedingly dry one, especially in many localities — so much so that our reservoirs became perfectly dry, and but few of the rains were sufficient in volume to fill them up. Under these circumstances the ground was simply excellently underdrained, and nothing more —that is, so far as the reservoirs were concerned. Mixing manure through the soil to a depth of 18 inches or 2 feet produces wonderful crops, as a matter of course; but our beds near the factory, where exhaust steam was permitted to go under them, were covered with such a depth of earth over the reservoirs that the roots of but few plants could reach the water. The reason of putting our reservoirs so low was, as I have before explained, to avoid injuring the plants by too much heat.

We commenced planting seeds and putting out plants, as you may remember, some time in February. Peas were planted in the open ground over these reservoirs, Feb. 10, and they yielded a crop of nice pods the fore part of April. Cabbage-plants taken from the greenhouse, and put beside the peas at the same date, were, for a time, protected by a sash to harden them off; but after two or three weeks they, too, were allowed to stand without any protection. They were repeatedly buried up in the snow, but the ground did not freeze, owing to the heat underneath. The plants made a vigorous growth, and were just as good as cold-frame plants, so far as I could discover. A few were left on this ground, producing heads of cabbage in April that weighed, some of them, 10 lbs.; and as we received for them 3 cts. per lb., we got 30 cts. for a few single heads of cabbage.

After the cabbage we put on beets and lettuce, of which I have written you. The lettuce sold readily in May at 5 cts. per head each. You will remember we started another crop between the rows when we were marketing one crop. After the lettuce, we put out cucumbers which were started in the greenhouse. It took some little time for the roots to get down into the reservoirs beneath; but when they did, they gave an enormous crop of cucumbers, which grew so rapidly sometimes that we picked them every day. These cucumbers, coming much in advance of any raised in the open air, sold readily at a good price.

After the cucumbers, we raised a fine lot of turnip-plants; and when these were put out in the open field the bed was cropped with lettuce, which now covers the ground, and the plants are so large and thrifty that they are an astonishment to every passer-by. The year is not up yet, and will not be until next February; yet this ground has given us *five paying crops*, and many of the crops not only paid, but they paid handsomely. Of course, the ground was heavily manured. The two feet of soil that covers the stone reservoirs contained, perhaps, six inches of manure; but, my friends, will it not pay, and especially will it not pay for those who have *time* on their hands, with nothing to do? And this book, as you may remember, is written mainly for this class.

A squash-vine, started in the greenhouse, and put out in June, made very slow growth for a time, but it finally started an immense squash, which in time got so heavy that it broke the vine that bore it — said vine being run over a trellis. I told father Cole about it, and he said I should have made a platform or shelf under the squash. Another one grew to an enormous size, and we finally sold about half a dozen in all from one vine. The quality was excellent.

Some time in the latter part of July or fore part of August a pumpkin-vine came up of itself. Nobody thought it could possibly ripen any pumpkins; but the single vine produced six, and ripened them all. The growth was most astonishing. I presume vines of all kinds send their roots down at once into the reservoirs; and when they get there they make a growth that is really surprising. Some strawberry-plants were started in March, and they bore a crop of fine large berries, but we expect greater results from these next season. Pie-plant promises wonderfully. We have not tested the matter on asparagus, but propose to another season.

Such a plot of ground may be worked on, not only evenings, but on rainy days. If it rains hard, fix a temporary covering over you, of the shutters or sash, used in the winter time. Of course, the aid of exhaust steam, such as we use, will not very likely be at the command of many of our readers; but this exhaust steam is of no particular use from the first of April until the first of October; and by the aid of sash we can make plants grow nicely through March and October — yes, and through a great part of November, without bottom heat, especially where we have ground that is enriched to two feet in depth.

Perhaps the greatest satisfaction I have received in the use of the New Agriculture has been in making the swamp-holes and waste places on our 18 acres the most productive spots we have. When I bought the place, a small stream which we call Champion Brook meandered across our low ground, traveling over more than twice the distance it would make in going straight across, as such brooks usually do. In fact, our whole creek bottom has been at different times washed over and cut up by this Champion Brook. Well, my first work six or seven years ago was to make Champion Brook go straight from where it came on to my land, to the point where it passed off. This left the old creek-bed, and in many places it had washed great holes down to the bed-rock. These holes have been a bother and a nuisance until the present season. During the past summer, as I have told you, we have scooped out the contents, clear down to the rock, in many places, and I tell you it was real fun to do it — especially as the dry season greatly favored the work. These holes were then a receptacle for all the stone, tinware, boots, and shoes, and every thing that could be collected on the place; and during the past season we have been grubbing out the stumps, and using them to fill these gullies and holes. We make the surface level, then cover it with tinware, or something that will not decay, then down come the banks to the sides, until we can run both plow and cultivator right over them, without any danger of striking or tearing up the stumps or tinware. Of course, these holes are full of water, or, at least, as full as the outlets described in Chapter V. allow them to get. We want the water to come within a foot or 18 inches of the surface of the soil, but no higher. Our crops over these places have been wonderful. I was pleased to see even friend Terry express his admiration and satisfaction at the looks of my potatoes, celery, and other crops. Celery seems to revel in such a situation. Our plants on the creek bottom are to-day looking as bright and green as they have been during any part of the year, and it is now the 2d day of November. Last week we dug some roots that weighed fully 3 lbs. each. At 5 cts. per lb. this is 15 cts. per root, which makes quite a satisfactory return for labor and capital employed.

In order to see whether our celery compared favorably with the best raised anywhere else, I have had samples of the finest from Michigan, from Cleveland, O., and even from the Arlington market-gardens, near Boston. Some of the Arlington celery weighed 3 lbs. to the root; but it was on account of the enormous suckers growing around the sides. I should call ours ahead of any thing that we have seen. Of course, fine tilth, with plenty of moisture, and not too much, are not the only things wanted: we must have manure also; and I think it will pay well to manure the very best ground that can be found anywhere—at least, such is my experience. And this brings us to a second consideration of the subject of manures, for our next chapter.

CHAPTER XXIX.

And the dresser of his vineyard said unto him, Lord, let it alone this year also, till I shall dig about it, and dung it.—LUKE 13:8.

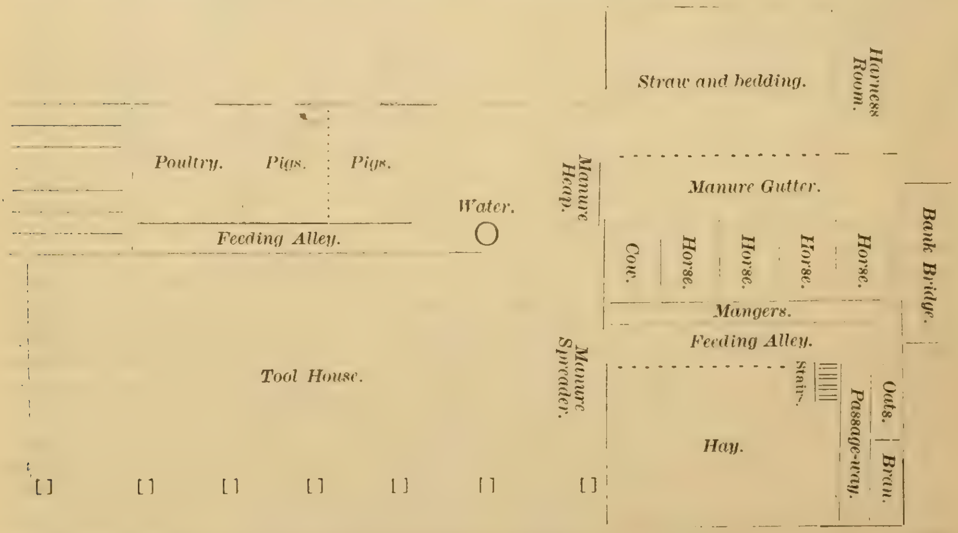
I have given the above little verse a place here, not to point you to the moral contained in the parable, but to call attention to the fact that it was customary, even at the time the Savior was upon the earth, to use the dung from animals for enriching the soil, and for the encouragement of vegetation. In former chapters I have given you something of a talk on manures. In this chapter I propose to discuss saving and making manures on our own premises. Of course, the market-gardener will expect to buy a good deal of manure; but as a penny saved is a penny earned, he should by all means economize every scrap and every product on his own place. I used to think I never wanted a pig on the premises; in fact, my taste did not run that way. When I was a boy it used to be my business to care for the pig, and perhaps I naturally became prejudiced, because it was a kind of work I never enjoyed. A great many times I forgot to feed the pig. How differently we look at things when we become an interested party! For a good many years, one after another of my men would tell me, "Mr. Root, you should keep a pig;" or, "Mr. Root, you throw away trash enough all the while to keep a couple of pigs," etc. Finally, some of the older men whom I employ, and who have probably had more or less experience in farming, would remark to me, that there was nothing like hog-manure to make certain vegetables grow, etc. Very often I would reply, that I would not have them grow if they could not be managed with something a little more pleasant to have around; but since I have got the gardening-fever, we are pressing into service almost all kinds of domestic animals—the horses, cow, poultry, and, finally, the pigs. During the past three months I do not think our pigs have had a scrap of any thing except the refuse that would have gone into the compost heap direct. When the pen gets to smelling badly in hot weather, we throw in some dry straw or litter, or the coarse manure from the stables; and in a twinkling the pigs roll it over and over, and mix it up more thoroughly than any gardener could do it with spade and fork, if he tried ever so hard. When the accumulation is sufficient, it goes into the manure-spreader, and the Acme harrow quickly mixes it up with the fresh dirt.

May be, my friend, you are a poor man, and have little or no live stock about you; but I can hardly imagine how you can be too poor to afford to keep a pig: yes, a pig and some chickens. Perhaps the chickens might come first, because they pay back your money almost the first day you get them. Piggy does not do as well as that, but it does not cost very much cash out to keep him, and he is always worth a certain amount of clean cash, even if he is not a very clean fellow himself. A pig may, however, be managed so as to be a tolerably clean animal. You do not want any ring in the nose of your pig. Our first pair of pigs came with rings in their noses. For our ranch we want the best rooter that can be procured; then give him a good pen, and dump in the rubbish. If you are so unfortunate or so thoughtless as to let weeds grow on your premises, gather up the weeds and give them to piggy. Have a pail specially for piggy's use; and I think it will be a very good thing to have the word "Piggy" on this pail; or you can put it "Piggy's Pail," if you choose; then get all the family interested in seeing how much of a contribution can be made for his pigship. Give him all weeds, grass from the roadside, leaves from the forest and fruit-trees. Save every rotten potato, every apple and apple-core, shells of nuts that the children have cracked, potato-peelings, potato-tops, cabbage-leaves, cabbage-stumps, melon-rinds, pumpkin-parings, and every thing you can think of that is fit to eat, or that will decay when composted. Piggy's yard will be wet enough without the addition of water to the compost, especially if the yard is not covered over; and whenever it gets too wet, put in some absorbent such as peat, sawdust, straw, forest-leaves, or any thing of that sort. You and he are going into the manure-business, and both of you are to see how much can be manufactured, and of the very best quality. If you keep a horse, you can give the pig the bedding, together with the manure that comes from the horse-stables. If your poultry-house is near by, I think it an excellent plan to let piggy stir it up with the horse-manure also.

A question comes in just now that has been largely discussed at farmers' institutes, and through agricultural papers.

WHAT IS THE BEST PLAN FOR SAVING MANURE?

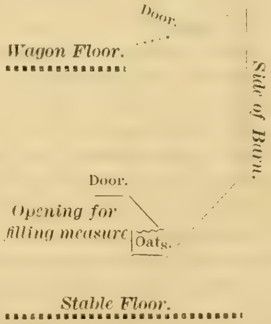
I believe that the general decision has been, that it pays to have manure under cover. One thing is very certain, however, and that is, that it does not pay to let manure of any kind get hot and burn up. Manure that is well worth a dollar a load may be, by a little carelessness, soon made worth no more than 25 cts. a load; and if you leave your manure exposed to the weather, its value largely depends upon the amount of rain. If the manure is spread out so the heap is level on top, and not too deep, it may catch rain enough to cause it to decompose nicely; but I think this is too hap-hazard a way. Our best authorities, in fact, seem to agree pretty well that a much safer way than this would be to spread the manure on the land just as fast as it is taken out of the stables, and may be this is the proper way to do it in any event. It is, however, a pretty hard matter to carry the manure to the very spot you want it, as often as you clean your stables. The weather may be unfit, for instance. On this account I would try to have the manure-bed under cover; and I would, if possible, have abundance of water so near by that you can wet the heap whenever you find it needful. Stirring up can be done cheaper by the pigs than in any other way. Perhaps it may be well to state, before we go further, that a good many might object to the quality of the pork, providing the pigs were used simply as machines for making manure. But, do not be in haste, dear friends, to condemn our methods. When you get ready to fatten a chicken, a pig, or a "critter," you want to commence a system of feeding, to produce nice meat. I believe that corn-fed animals are considered worth most in the market; and friend Peirce, who wrote our book on carp culture, once assured me that the Jersey chickens, which commanded a better price in New York, Philadelphia, and Boston, than any other chickens, owed their well-earned reputation to the fact that, before being sent to market, they were fed for several weeks on corn diet exclusively. Even our new food fish, the German carp, require some such treatment to have it do its best as a table fish. Well, if we are going to be obliged to keep our pigs exclusively on corn for several weeks, what shall we do with our refuse matter meanwhile? Why, my friend, you want your pig-pen in two apartments, and keep those animals which are under process of fattening, in a separate apartment from those used exclusively for manure-making. In fact, I have just bought two more pigs today, to take the place of those that have not had a particle of any kind of grain, or even bran or middlings, for the past four months. Now you see we are coming to the consideration of the matter of pig-pens, poultry-houses, cow-stables, and horse-stables. My barn, stables, pig-pens, and poultry-house, were all burned down last March, so I have had an opportunity this summer of building entirely new. When I began to consider the subject in all its bearings, and to read the books and papers treating especially on these matters, I came to the conclusion that it was a very important matter indeed to have convenient buildings; and as friend Terry who wrote the Potato-book, and the book on the winter care of horses and cattle, lives less than forty miles from me, I wrote him to come and help me plan my new barn with the other buildings, and that I would pay him well for his time and trouble. He not only came promptly, but he brought another man with him who is a prominent teacher through the agricultural papers, in the dairy-business. I mean Mr. Gould. This gentleman is the one who writes for the *Ohio Farmer* under the name of "Sam." Mr. Terry sat down by the side of an experienced builder, and, with the assistance of a man who is also conversant with horses, we fixed upon the plan which I illustrate by the diagram below. The barn is now built; and so many judges have pronounced it the most convenient barn and stable that "ever was," I feel that it may be a help to have you look it over with me.



BARN, HORSE-STABLE, PIG-PEN, AND POULTRY-HOUSE, DESIGNED BY T. B. TERRY, OF HUDSON, O., WITH SOME ASSISTANCE FROM THE AUTHOR OF THIS BOOK.

We will commence with the horses, for they are not only the largest producers of manure, but, I believe, for general purposes horse-manure is considered the best manure. The horse is usually the most important personage in the barn, or among our domestic animals. In our diagram I have shown places for four horses, although we use only two, as a general thing. When work is crowding, or if one of the horses should happen to be temporarily disabled, we get another horse from a neighbor; and then it is very handy to have an extra stall for a visitor's horse or horses. Of course, many of the friends will not want so spacious outbuildings as I have figured, but the principles can be carried out with the smallest stable, pig-pen, or poultry-house.

What shall the horses stand on? was one of the first questions I asked friend Terry. He replied, that the best material for the stable-floor that he knew of was made of small stones and gravel, filled in with cement, but that he would lay inch boards in the stall (over this stone floor) for the horses to stand on, as the wood is drier and warmer than the stone floor. The gutter for manure back of the horses is clean stone (or cement), but sunk a little so it will take all the moist and liquid portions of the manure. Right back of the cow-stable there is a sliding-door that communicates with a sort of box stall, where the manure is piled until it can be drawn out. The manure-spreader stands in the tool-house, ready to be backed up to the manure heap at any time, or it can stand in the place of the manure heap. the manure being pitched from the stables on to a wheelbarrow, and then run right up to the spreader. This box stall, as we call it, is also the general watering-place. Ours is fed by the water-works of the town; and it is very convenient indeed to have running water. Where there is a spring, it can often be brought into the barn in this way. If there is none, have a well or cistern about where I have marked, Water. If you have a couple of bars across from the watering-tank to the cow-stable, you can turn the horses and cattle loose in this box stall, and let them drink at their leisure while you are cleaning the stables and fixing the bedding. Right back of the horses and cattle there is a bay for straw and bedding. Before cold weather comes, this bay should be filled clear to the upper floor. The bay for hay on the opposite side of the barn should also be filled to the upper floor. Then the stock have a wall behind them of straw, and a wall in front of them of hay, a bank bridge on the north, and the tool-house and manure-shed on the south, while above them is the main floor on which teams go in with hay, straw, oats, or other produce. You see this makes a pretty warm barn, even if built on level ground. The bank bridge is walled up with stone, about ten feet back from the barn. The bridge itself is matched plank, put together with paint, so it is water-tight. The sliding-door under this bridge gives access to the stable, so you see we have a sort of "storm-door," as it were, to keep the wind from blowing in when the stable-door is opened. There is also a sliding-door opening from the stables to the manure heap. The feeding-alley is just wide enough to allow one to pass and feed the animals conveniently. The oats are close to the feeding-alley, in a bin that holds about 600 bushels. A little door at a convenient height opens into the passageway, and you can dip up a measure full of oats by reaching in this little door, so long as there are any oats in the bin. The accompanying diagram will show you how the opening is made:



A CONVENIENT OAT-BIN FOR A BANK-BARN.

Another similar bin is made for bran, corn, or whatever else you choose. You can have a barrel of salt at the further end of the passageway, near the bran-bin. The stairs lead from the feeding-alley on to the upper floor. We are using the fanning-mill to-day on the upper floor, and it is placed so that the chaff and dust all flies over into the straw and bedding mow. In fact, we throw every thing into this heap of straw—rubbish of all kinds, left after saving the seeds of garden vegetables, husks, chaff, etc. Some may object, that the seeds may, by this means, get into the manure; but with the thorough cultivation we give our field crops we do not feel very much afraid of plants that are not wanted. They will have a tough time of it to make a growth, even if they try. The manure from the cow is handled exactly like that from the horses; and we think it an excellent plan to have it mixed in with the horse-manure, to prevent heating. Now, the shed that covers the manure heap is prolonged, as you will observe, so as to make a sort of "box stall;" and directly south of this "box stall" are two pig-pens. One of these is for the pigs that are large enough to be given grain, with a view of fattening. The other is for the little pigs that have the trash. There are sliding-windows to communicate with the open air, opening into each one of the pig-pens. These windows are for ventilation, and to permit unloading rubbish from a wagon or wheelbarrow, directly into the pig-pen. Manure can be thrown out of these sliding-windows also, or the manure-spreader can be backed around against the pig-pen nearest the water-tank. If your pigs are disposed to be friendly to each other, the passageway between the two pens can be opened, permitting them all to run in together. If you have a gate to this passageway so it will operate easily, you can fill the feeding-trough for the pigs in one apartment while they are in the other. Then open the gate and let them through. In this way you can oblige them to behave themselves a little decorously while you are pouring the feed into the trough. Of course, there is a trough for each apartment; and as the pigs generally all go into one apartment or the other, you can put your feed into the trough belonging to the vacant apartment before you open the sliding-doors.

Beyond the pig-pen we come to the poultry-house. This has a sliding-window of double width, or, rather, two sash, one sliding to the south and the other to the north. Besides this, at the south of the poultry-house proper is a little room, all covered with glass, greenhouse fashion. This glass reaches from one foot above the ground, up to within about two feet of the ceiling of the roosting-apartment; and under this sash the fowls are supposed to stay during sunny days in the winter time. I have figured a good deal in regard to nests and feeding-boxes, and have finally concluded that the best nest for hens I know of is a barrel half filled with oats. You may have barrels half filled with buckwheat, wheat-screenings, or other grains, if you choose. If your hen's-nest gets soiled and dirty, let the fowls eat up the grain, burn up the barrel, and get another one. If you object, that rats and mice can climb up the sides of a barrel too easily, have a barrel made with the sides of cheap tin. Your tinsmith has very often rusty or damaged tin that he will sell at a low price. Such a hen's-nest can not very well be infested with vermin—that is, if the contents are renewed often; and if it is grain for fowls to eat, I presume it would be. This fowl-house was intended for the fowls to run out whenever the weather permits. The roosts are on the north side; and during very severe weather a curtain of some cheap coarse cloth, such as burlap, may be let down over the greenhouse sash, and also over the sliding-windows. The wall of the partitions, as well as the ceilings, is protected by matched ceilings and tarred paper.

With the above arrangement you have your domestic animals comfortably housed, and so conveniently distributed that feeding is only a pleasure. You have plenty of room in the tool-house for all of your tools, machines, and wagons, used on the premises. A full description of this tool-house will be found in our book, "The Winter Care of Horses and Cattle," p. 720, 1885. I confess I feel a little proud of this arrangement for farm stock; and, simple as it seems, a great deal of hard work was done on it before we decided on its present form. If you have ever noticed it, the amount of time required to do the work about the barn—hitching up teams, feeding and watering, is such that it is of the greatest importance that we have things handy. With such an arrangement as the above, you might do in 15 minutes the work that would require *one hour*, with poor facilities, before you could start in for a day's work. When the plan was worked out we had, in fact, a little *convention* of practical men. First, we had friend Terry, who has been studying on this problem for years. Then friend Gould, who is a dairy-man, and who has made the care of cattle his lifelong study. Besides, the foreman of our wood-working factory, who has had some experience in planning and making buildings. Then my neighbor Harrington advised some, and he is a farmer of many years' experience, as well as a bee-keeper. The man who has care of our horses also gave many suggestions in regard to the stables, conveniences for water, feed, etc.; and he is one of the best men to take care of horses I ever met. The practical workings of the building please us so much I do not know of a thing that I would have changed.

I have told you how we get in our hay and straw. Well, suppose we have a load of oats to put away. The load is driven up the bank bridge on the main floor, right over the horses; the door to the oat-bin is swung back, and the bags are emptied right off from the wagon, right into this bin. The oats are never handled any more until they run themselves right down within arm's reach of the horses' manger. These bins for grain are made rat-proof. The cement floor makes it impossible for rats to dig holes in or around the barn. If rats or mice trouble me in the poultry-house I will put wire netting about six inches underneath the surface of the ground which forms the floor. I greatly prefer a dirt floor for fowls. A deep trench around the outside keeps the water away so the inside is always like dry dust. Peat from the swamp forms a good absorbing material to be placed under the roosts.

Now, then: The horses do our work and manufacture an excellent manure; the cow furnishes milk and butter, and also contributes largely to the manure heap; the pigs chew up and dig up all the trash and refuse from the table or the garden, orchard, etc. They convert this into manure, and give us pork, ham, etc. The poultry, next door, furnish eggs to go with the ham, and also give us a very valuable addition to the manure heap, before mentioned. The pigs work it in thoroughly, stirring it up without charging a cent. The business of the owner is to reward these friends of ours for their contributions by giving them nice clean warm quarters, perfectly protected from the weather, abundance of good food at just the proper time, and (I hope) lots of encouraging and loving words. He certainly can afford it, even if he does not—don't you think so, my friend? Is it *your* custom to make friends with your horse, your cow, your pigs, and your chickens? All these friends of ours are fond of a variety in their food; and they appreciate, more keenly than many people imagine, any little act of kindness in the way of delicacies. Almost any horse will learn to beg for apples whenever his keeper comes around him, after he has been treated to fruit just a few times. Apples that have been blown off the trees by the high winds can frequently be purchased at a very small price. We have just bought a load of forty bushels, at only five cents a bushel. A good many of them had commenced to decay after they were gathered, was one reason why we got them at this low price. Well, we commenced giving them to the horses, at the rate of about a peck a day. We soon found the Jersey cow, too, was very fond of them; and finally the chickens gave us to understand that they relished fruit also, by getting up on to the wagon and pecking the very largest and nicest apples on the load. We took the hint, and now they have all they want to eat. To-day it is stormy and cold, and the ground is covered with snow; but the chickens are under their glass sash, scratching wheat from among a pile of forest-leaves, and pecking apples for a change. Even the pigs, too, receive their share of the big forty-bushel wagon-load, and I am inclined to think it would be a good investment, even if the apples had cost us ten cents instead of five cents. Dear reader, is it true, that you let apples go to waste on the ground, when your horses and cattle, chickens and pigs, will appreciate them, as our domestic animals do?

CHAPTER XXX.

And let them have dominion over the fish of the sea, and over the fowl of the air, and over all the earth, and over every creeping thing that creepeth upon the earth.—GEN. 1: 28.

It is really surprising to see how often these four kinds of dumb friends of ours that I have been talking about in the preceding chapter can be brought in play to aid the market-gardener. As an illustration: We now sell potatoes on our market-wagon, and it has not taken us long to learn how quickly good potatoes go off at a good price, where poor and indifferent ones will hardly sell at all. One great trouble with potatoes is the damage occasioned them by grubs. Very often the nicest specimens you raise will be gnawed into, and made unsightly-looking, by these same pests. What is the remedy? Well, some tell us there is no remedy. If you raise potatoes on sod ground, you will have them scabby and eaten. But, hold on a bit, my friend. Suppose you have made friends of your chickens, so that they like to be around you. We have just been plowing on the creek bottom, and I noticed, as the nice ground was turned up, one of these grubs. I got an ear of corn and called my flock of Brahmas. A few grains scattered in the furrow after the plowman, did the business. After that the chickens were up (and dressed and had their faces washed, so to speak), ready to follow the plow as soon as the first furrow was turned in the morning; and didn't they look animated and happy, as they gobbled up the grubs—yes, and worms and insects of other kinds? Pretty soon the three hens that stole their nests, and gave me three broods of chickens in September, found out what was going on, and they, too, began following the plow. Of course, there are times when it is not so pleasant to have the fowls chasing after you. Then you want to shut them up in a spacious yard made of poultry-netting. But by a little planning you can have them to clean your ground pretty thoroughly of most of the pests of the kind I have spoken of. I have been told, that a flock of ducks will rid a large patch of potatoes of the potato-bug, but I have never had an opportunity of testing the matter. If this be so, it seems to me that friend Terry could afford to buy a brood of ducks, instead of employing so many men and boys to do that which the ducks could do so very much easier, quicker, and better. I have told you, in former chapters, how we employ very small chickens to rid the greenhouse of the green fly.

A few days ago a friend was discussing as to whether a garden can have too much manure. He said the result would be, the ground would be so full of angle-worms that nothing could be raised. This may be, in some measure, true; for angle-worms have troubled us by getting into the stalks of celery on our most heavily manured ground. I do not know that they do any harm, but they alarm customers, when they find there are worms in the celery. Another thing, I think very likely that angle-worms consume a valuable portion of the manure. Do you want to know the remedy? Gather all the fowls on the premises about you, then plow, cultivate, and harrow the ground where the angle-worms are troublesome, and I think the biddies will clear them out to your perfect satisfaction, and at small expense.

The finest plum-orchard I ever saw, I believe, was in a poultry-yard. Enough poultry was kept so the ground was perfectly bare under the plum-trees. Not a weed nor speck of vegetation of any kind could obtain a foothold. As a consequence, the curculio, when shaken from the trees, was captured by the fowls, which had thoroughly learned the trade. And, in fact, they not only gobbled every weed as soon as it showed itself, but they took every thing in the way of an insect from the smooth hard ground. The poultry paid a good profit, and the plum-trees bore enormously. The ground was, of course, underdrained, and fertilized up to a high state of cultivation before the poultry-yard was established. Mr. Jas. Mattoon, of Atwater, Portage Co., O., is the man who owns the plum-orchard and poultry-yard, and he told me he had just received $200 for his plum-crop.

The apple-worm, that is such a pest to fruit-growers, is the larva of the codlin moth, and for a time it seemed as if there were no remedy for wormy apples. By keeping pigs, however, under the apple-trees, in the same way that friend Mattoon keeps the poultry under the plum-trees, every wormy apple is devoured so quickly that no larva ever reaches the moth stages of existence, and in the course of time the orchard bears large fine apples, without any worm at the core. It is not at all likely that this subject of making these dumb friends of ours assist in destroying the insect-enemies of fine fruits and vegetables has by any means been fully explored; but rewards like those I have mentioned above are in store for the man who loves his poultry and pigs, and cattle and horses. Study their habits; study their tastes; recognize them as your neighbors, given by a wise and kind Father, to minister to our comfort and happiness, and you will find, on more intimate acquaintance, that they have abilities and qualifications to assist you in your work; yes, even during some of your grievous trials and troubles, that you would never dream of had you not cultivated these intimate and friendly relations of which I have been speaking.

To be continued Dec. 15, 1886.

HEADS OF GRAIN
FROM DIFFERENT FIELDS.

WHICH QUEEN IS IN THE HIVE?

I AM at a loss to know which queen reigns in a colony of bees I have. The colony was made some time in May, with a cell ready to hatch. Some ten days after, I opened the hive to see if the queen was laying. The bees balled the queen on sight. I gave them some smoke, and they released her; but that was the last I saw of her. I gave them queen-cells at different times through the season, but I could never discover any queen or eggs; but when I extracted buckwheat honey I gave them combs containing drones ready to hatch, which they accepted, also some brood of worker-bees. On receiving a Carniolan queen from F. Benton, I thought this colony would receive her gladly. After caging her 24 hours, as the bees seemed all reconciled to her, I released her; and 24 hours after, I found her, or another queen, at the entrance, dead. On giving them a frame of brood they began to build queen-cells; but I thought I *would* have my way, so I sent to Dr. Morrison and got a $1.00 Carniolan queen; and after destroying the cells I introduced No. 2. In 24 hours they had released her by eating the comb under the Peet cage, and a dead queen was at the entrance. As it was late in the season I gave up trying to queen them. But when fixing them for winter I found they had a large yellow queen, and no brood. She had been balled, as she was minus the fine hair on body, and her wings were badly split. Now, I am badly puzzled to know which queen is in that hive. S. HEATH.

Rimer, Pa., Nov. 5, 1886.

Friend H., I am inclined to believe that both the Carniolan queens you introduced were killed, and that the queen they now have is another queen. It is not uncommon for a young queen, after her wedding-flight, to return to the wrong hive, and therefore I think the present queen simply came there. No doubt she had been balled; but if bees are left to themselves they will sometimes let the queen alone, even after balling her. Next season's progeny of this queen will tell you whether I am right or not. As it was late in the season, you found no brood in the hive.

WHAT SHALL BE DONE IN CASES OF SEVERE STINGING?—IMMERSION IN WATER EFFECTIVE.

I noticed in GLEANINGS, page 667, the question: "What shall be done in case of severe stinging?" While placing my bees on their summer stands last spring, one swarm "went" for the hired man, and somehow got under his bee-veil, and stung him on the right cord in the back of the neck, and on the septum of the nose. Very soon he became blind, and his left side seemed touched with paralysis, and he fell to the ground. He was seized with a dreadful sensation, and throbbing in his head, and violent wrenching in his stomach. Great drops of perspiration stood out on his forehead, and his face became as spotted as an adder. I ran to the house for the camphor-bottle (I had seen this used with good effect while assisting at the amputation-table in the army, in the late war). It was the only available remedy at hand. I sopped the camphor all over his head and face (eyes excepted). By that time aid arrived, and we took him into the house. We at once gave him a few drops of spirits of camphor in some water, and in about ten or fifteen minutes we gave a second dose in whisky. We were about to send for a doctor, as we all began to think he would die; but the second dose of camphor went to the spot, and so far relieved him that all fear of death was passed; but it was not until the next day that he could get about. No doubt this was the effect of a nerve being stung; but for a flesh-sting I have found water to be better than either carbolic acid or borax. In most cases, if water or saliva is applied it will prevent any swelling; and if kept wet it will soon stop all pain. A neighbor says, that when he was a boy he once assisted a veterinary surgeon to relieve a valuable yoke of oxen. The oxen turned over a bee-hive, and the enraged bees stung them all over until the owner supposed they would die. The surgeon ordered the oxen to be wound up in carpets dipped in water. They were then driven into the river, and water was bailed on them until they were relieved. Water seems to enter the cavity made by the sting, and dilutes the poison until it is rendered powerless. It also reduces the heat which is caused by bee-poison. Why should not water be a good remedy for bee-poison, if hogs can cure themselves of rattlesnake-bites by lying in the mud and water until the poison has lost its deadly power? G. A. FARRAND.

Rockport, O.

Friend F., do you not see that, in the cases you have cited above, it is almost if not quite impossible to say that the sufferers would not have recovered just as soon had nothing been done? Don't think me contrary or headstrong in the matter; but I earnestly desire to get at the exact truth. I have tried water—cold, warm, and hot—for bee-stings, and I have tried it by immersing my hand right in the water, when stung, until I am sure the water has no effect on *myself* whatever. A sprain or a bruise is relieved instantly by immersing the part affected in water as hot as it can be borne; but with me, the same treatment does not seem to touch the poison of the bee-sting at all. Where bee-stings produce dangerous symptoms like those you mention, I do not know but that I myself would try the remedies you suggest, because it seems terrible not to do any thing at all when a friend is in such distress and danger; but for all that, the experience I have had strongly inclines me to think that neither water nor camphor, nor, in fact, any thing that I know of, unless it be extracting the sting as quickly as possible, has any effect whatever upon the pain or swelling. It is exceedingly important that we should have all the light we can get upon this subject; and I would therefore recommend that intelligent bee-keepers make thorough and extensive experiments to enable us to decide what to do in case of severe stings, or to decide if there is any thing we can do to help the matter.

A POINTER ABOUT EXTRACTING, AND HOW TO PREVENT ROBBING.

About two weeks ago I extracted honey from 5 hives, and placed the combs *back* on two of the same, taking away the combs and upper stories *completely, from* 3 of them. Now for the pointer: The two where I placed the combs *back* had a considerable row with robbers, while I did not see a single robber around the other three. Do you not think that my cleaning up the hive so as not to leave a scent of honey prevented the robbers from discovering any thing wrong with the three, while the scent of the extracted combs in the others attracted the robbers? This may not be worth much to the veterans, but I consider it worth a good deal to the novice. M. BROERS, 3—24—27.

Gonzales, Tex., Nov. 2, 1886.

I have observed the same thing before, friend B. Thanks for your calling attention to it, nevertheless. It seems to me, however, you do not finish the subject. If we take combs away from the bees, without putting any empty combs back after the honey has been extracted, there will be no robbing, but what shall we do with these empty combs? I would say, Return them by moonlight; and before the bees are flying next morning, every thing will be cleaned up and put away.

THE STENCH FROM DEAD BEES; CATNIP, ETC.

GLEANINGS is always a welcome visitor, as you, with the assistance of a corps of writers, give us A B C fellows no small amount of information we so much stand in need of. I am glad you have got ahead of your foul brood. My bees are all right now, though some time since, when I raised the cover of a certain hive, the stench that came up from dead bees made me sick, for I had been reading of foul brood. I thought I had it; but it was old bees that were dead, not brood.

If it had not been for friend Higbie's catnip, our bees in this section would have died this winter, or would have had to be fed their winter supplies; but they are all right. I agree with friend Swinson, that it won't do to go for "big ads" all the time. He filled my order last spring for queens, when some others were months in doing it. Let me say, that I got one of the best red-clover queens of him I ever saw, if such queens exist—at least, her bees made honey from red clover when none of the others did. W. K. JAMES.

Loudon, Tenn., Nov. 7, 1886.

MY METHOD OF UNITING WEAK COLONIES.

The colony I wish to keep, I prepare to receive the new colony by simply turning up a small corner of the enameled cloth at the back corner of the hive, and then set the one to unite on top, and leave them two days. Then I remove the cloth from between them, and in a day or two, as convenient, I arrange their brood and comb as desired. By this method very few bees will ever leave for their old stand. Sometimes I put several stories on top this way, or as many as I may wish to make a colony to suit my purposes. My management, first, is for queen-rearing in early spring—February, March, and April. All queens that I can raise then are sold, so that I have only enough left to leave one queen to three or four nuclei, which I pile on top, as above named. Then I am ready for honey with rousing colonies; for my nuclei contain 10 frames, 9⅛ x 13½ inches, outside dimensions. In September I break them up into nuclei again, and rear as many queens as I can, and what I lack I have been buying—some of our Kentucky friend, J. T. Wilson, of Nicholasville. By this management I winter many more queens than I could do in any other way that I have practiced. I use a Simplicity hive, only I use a shorter frame, which, if I remember, you at one time called "crosswise Langstroth." JOHN CRAYCRAFT.

Altoona, Orange Co., Fla., Oct. 11, 1886.

Your method of wintering weak colonies is essentially the same as the one we have practiced. See department of Our Own Apiary in back issues.

ALSIKE FOR ENRICHING THE SOIL.

Can any one who reads GLEANINGS tell any thing about the fertilizing qualities of alsike? I have read much about the delicious sweet it produces, but never a word about it in regard to enriching the soil, which is a very important thing. Why can't those who have had experience in the matter just tell us what they know? Don't you see the point? How much more seed would be sold, if we could say that it is as good, if not superior, to any thing else as a fertilizer! As the time for sowing will be upon us soon, we must prepare for it. In so doing we must sow that which will give the best returns for money invested. J. A. RIME.

Fairfield, Adams Co., Pa.

Friend R., I have not known of alsike being plowed under, as we do the large red clovers, for the reason, perhaps, that the seed costs too much to use it in this way; besides, it would not furnish as much material to plow under as the Mammoth red clover, which does not cost nearly as much per bushel. As to its effects in bringing up poor soils, I think it will compare favorably with the rest of the clovers. Perhaps some of our readers have tested it.

HOW TO SELL HONEY; AND A FEW KIND WORDS AS WELL.

The complaint of "no market" for honey is heard here, and will continue to be heard until the producer will gird on his armor and sally forth, determined to sell at the front or back door of every house. We have determined to peddle our honey in St. Louis, and will commence about Wednesday of this week.

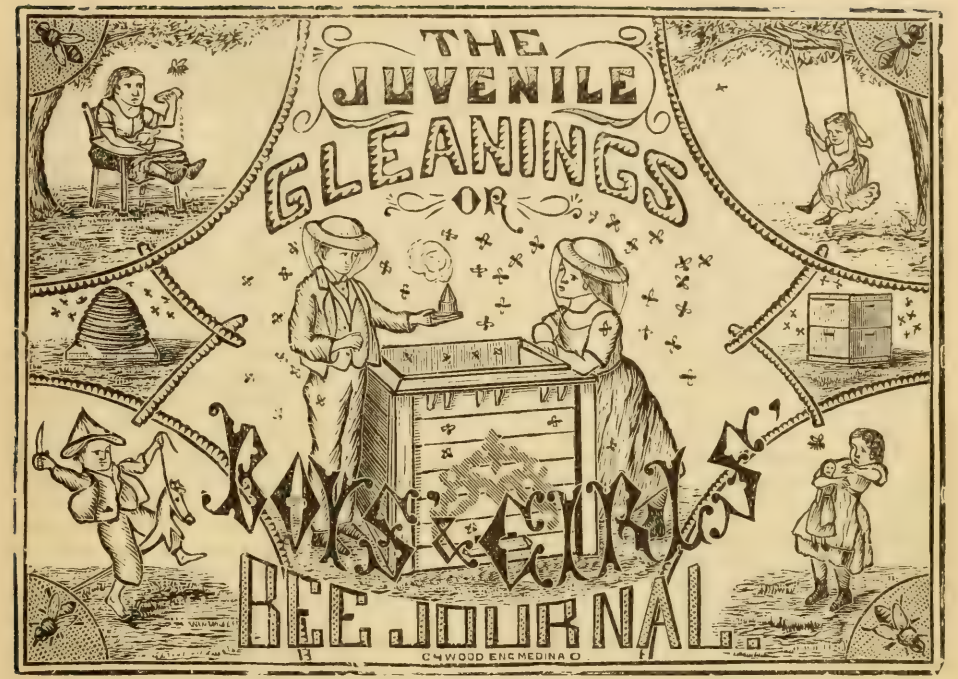
We receive GLEANINGS regularly; and as we read in it we are sensibly drawn to a higher appreciation of the moral solidity of the character of its editor, and of his great work in the fields of Christianity wherever he is known. Moved by a friendly impulse, our purpose is to write just as we would talk, could we be in Medina, and be present with you in the environments of your own home. In writing, the use of "we" does not signify that an editor is writing, but one who, in all the vast concerns of life, has a partner who is always consulted; and in our family it is generally "we," not "I"—only two in our family—wife and I.

Venice, Ill., Oct. 31, 1886. O. D. OBERLIN.

WHY NOT CLIP QUEENS' WINGS?

It does astonish me when any of the bee-keepers speak against clipping queens' wings, as I have practiced it for years, and think it the very axle on which the whole machinery turns—so little trouble to hive swarms, and so quickly done, if her wings are clipped. If not, you never know what to expect, as they invariably settle high in the timber around our yard, and getting them down safely and quickly enough is the next thing. But when the wings are clipped it is an easy task of only a few moments. MRS. A. V. CAMPBELL.

Middleton, Tenn., Oct. 28, 1886.



He that is faithful in that which is least, is faithful also in much.—LUKE 16:10.

MYSELF AND MY NEIGHBORS.

When they had dined, Jesus saith to Simon Peter, Simon, son of Jonas, lovest thou me more than these? He saith unto him, Yea, Lord; thou knowest that I love thee. He saith unto him, Feed my lambs.—JOHN 21:15.

ONE day, when I was tired of reading letters, I pushed off as usual down among the celery-plants, to see how the men were getting along. On my way I met my flock of Brahmas that I have told you about so many times. They looked so pretty and so slick that I felt a sudden desire to get one in my hands, that I might stroke the soft plumage, and make friends, in a general way, of these beautiful birds. I found an ear of sweet corn, left after we had gathered the crop for seed, and by a judicious use of it I soon had a fine Brahma prisoner. In a little time I succeeded in getting him to eat corn while I held him, and finally to eat out of my hand, and in just about 20 minutes by my watch I had him so thoroughly tamed that I could set him down and pick him up again. I had convinced him I was a friend and not an enemy, and I felt something of the satisfaction, when I started to go along to my work, that I often feel when I handle a colony of cross bees, without smoke or bee-veil. It seems like fulfilling the promise of Scripture, where God said, "Let man have dominion over them."

When I got back to the factory, a lot of schoolboys were running our lumber-car for play. It was Saturday afternoon, and they were boiling over with spirits, and wanted to do something. They had been repeatedly forbidden to use this car. In fact, the lower end of the track was torn up, and they not only endangered the car, but endangered their bones in using it to ride on. I felt cross to think they disobeyed; but they were so busy with their fun that I walked right up to them before they saw me. In fact, I had ample time to theorize a little before I said any thing. My thoughts ran something like this:

"Old fellow, you have just been boasting to yourself that it took you only twenty minutes to capture and tame a Brahma chicken; now suppose you try your hand at this flock right before you. Can you win *their* confidence, and tame them so they won't run when you speak, in twenty minutes, or even half a day? The chickens are only dumb brutes; but these are human beings, and have immortal souls. Yes, even that boy whose face is so dirty has a soul to be saved, and Christ died for such as he. Furthermore, the parting injunction of the Master, when he left his disciples here upon earth, was, 'Feed my lambs;' and now, then, old fellow, let us see you practice what you preach."

It almost made me tremble to think of the responsibility that rested on my poor self at this moment, especially when I realized how far away I had just been from the straight and narrow path. I began to be thankful that they *did not* see me till I had had time to reflect. Can you tame a boy as easily as you can a chicken? I waited until one of them looked up to me, and then they made a start to run; but by mild words I induced them to wait a little. I spoke to them pleasantly, and explained to them the reason why we could not permit them to have fun with the car; and as I looked into their faces, one after another, I was pleased to see that I had succeeded in bringing a smile to the face of every one. Yes, even the dirty-faced boy smiled too; but it was such a comic smile through the dirt that *I* had to smile in spite of myself. I don't think the boys have bothered the car any since. But the question is, What have they been doing meanwhile? I am obliged to say, I do not know; in fact, I haven't thought of them very much since then, unless once in a while, to wonder what I can do for them. I used an ear of sweet corn to catch the chickens. Is that a good way to catch boys? To a certain extent, I think it is; and I am well aware that I could get a whole dozen of boys any Saturday afternoon—boys brimful of good nature, and ready to do any thing I ask them to do, by the judicious use of a few nickels. Shall I hire them with money to be good boys? God forbid. I can do this, however: I have just purchased a peat-swamp (or a little one, at least), that lies in sight of where I am now writing. It is covered with small underbrush and little trees, and a great amount of gnarly roots. I want these roots and bushes chopped into firewood. Now, I could employ a dozen boys profitably, without much doubt, some Saturday afternoon, in clearing up this swamp. I shall probably need to purchase a dozen cheap hatchets, and, more than all, I shall need to be right with them personally. Although I have many good men in my employ, yet I feel pretty sure that I should succeed much better with the boys than anybody else. They would do more work if I were with them, and I am pretty sure, also, they would enjoy the work more. Now, then, dear reader, are there not Christ's lambs in *your* neighborhood—lambs that are full of restless energy, longing for some one to lead them, and ready, for any thing you know, to be led to Christ Jesus, if you and I can only have faith enough to accept the responsibility, and take hold of the work. May God help us to remember these *little* neighbors of ours!

WILLIE'S COMPOSITION ON THE BEE.

AS READ BEFORE HIS SCHOOL FRIENDS.

THE bee is a peculiar little insect. It feeds upon the honey secreted in the flowers of our roads and fields. It carries its honey to its home and stores it away in its cell to feed the young bees, and also for winter food. When the cell is full of honey they cap it over with a white capping, making it very pleasing to the eye, and delicious to the taste. A good colony consists of about 50,000 bees. A large bee, called the queen, presides over every colony of bees. In the summer time, in every colony are found lots of drones, which is the male bee. In the summer season, when the bees are gathering lots of honey, and the hive becomes crowded with bees, for want of more room they swarm out, making a wonderful uproar in the air; the queen is among the last to leave the hive. After roaring around in the air for awhile they usually settle on some branch or tree, when the good man or boy of the house puts them in a hive, and they are ready for work. The old queen having left the old colony, they now proceed to raise some new queens. About six days after the queens hatch out, we have what is called the second swarm, or after-swarm. In these after-swarms we sometimes find two, three, four, or sometimes a half a dozen young queens. We hive this second swarm as we did the first.

In the fall of the year, when the bees do not gather much honey, they rob other colonies. If the colony is too weak to defend themselves, the robber-bees will take all their honey; and for want of food they usually swarm out. We hive this absconding swarm, as it is called, as we did the first and second swarm. We hive the bees with a box with a lot of holes in it, and a long pole attached to it. We set the hiving-box by the bees, leaning it against the branch or limb which the bees had settled on; then we have a hook, with a long pole attached to it, to shake the bees off of the limb, and they usually settle in the box. After the bees are all in the box, we take them down and put them in a hive, and give them some brood, honey, and some foundation. We have all of our frames made so that they will fit all of our hives.

To prevent bees from swarming is to take an empty hive and lift half of the frames, bees and all, over into the empty hive, and give both colonies some foundation to work on. This is called transferring bees. The old queen having been took away from the old colony, they now proceed to raise some new queens. After the queens are about to hatch out, the man or boy of the house takes all of the queen-cells out but one, and makes a small bee-hive, with about two or three frames in it. He divides this as he did the first, and gives them one of the queen-cells and some brood and honey. After the queen hatches out they go to work. This small bee-hive is used in raising queens, and is called the nucleus hive. A good Italian queen is valued at $1, $2, $3, $4, and up to $6.00.

There are different kinds of bees. The common black, or German brown, the Italian, the Assyrian, the Holy-Land, and the Carniolan bee. The most popular bee is the Italian; the Carniolan is said to be the gentlest bee we have. The Assyrian bee is said to be the crossest—so cross that a boy like me had better keep hands off, if he don't want himself peppered with the venom of its stinger. The queen-bee is now shipped in cages through the mails from the old countries, even from the city of Jerusalem, where our Savior used to be, and brought over here and introduced in our hives.

So, now, young friends, I have told you about the bee. May we learn a lesson from the busy bee, and be always industrious as the working bee, and not as the lazy drone, who is stung and driven out of the hive. WILLIE M. BOLTON, age 11.

Stanley, Putnam Co., O.

Very good, friend Willie; but it seems to me your figures, 50,000, would make a rousing colony. The number laid down in the books is, I believe, about 40,000; but this would probably refer to a swarm in the spring of the year, pretty near swarming time. We have more colonies of bees that would run 20,000 than 40,000 even, in my opinion.

JUVENILE·DEPARTMENT

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN ON BEES OR OTHER MATTERS, will recive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from $1.00 to $1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

> "A chiel's amang ye takin' notes;
> An' faith, he'll prent it."

JIMMY'S TROUBLE IN FEEDING HIS BEES.

"THE bees is swarmin'!" said Jimmy's little brother Ted.

"Guess you're mistaken — wouldn't be no swarms in the middle 'f October," said Jimmy, as he started with a bound toward his four hives, leaving his little brother trudging after.

"Vell, I guess they be," persisted Ted, almost out of breath.

"Ouch! cracky! Ted, you run for the house, or you'll—my! how savage they be!" shouted Jimmy, as he made a great effort to stand his ground. Ted did not obey immediately; but a moment later he set up a roar —such a roar as only a seven-year-old youngster can give when stung. Jimmy, in the meantime, paid no attention to the cries of his brother.

"Oh-um! how that *does* hurt!" said Jimmy, gritting his teeth, as he pulled a sting from under his finger-nail. Bizz-zip! and a bee sent his little dart in his eyelid, and a third on his upper lip. The tears streamed down his cheeks, as the pain coursed through his eye; and to say that he felt like sneezing, and couldn't, does not half express it. Ted continued to roar loud enough to rouse the neighborhood. Perhaps half a dozen bees were now buzzing about Jimmy's head.

"Cracky! I can't stand no more o' this," he thought; and with two or three bounds he dashed into a thick clump of bushes near the fence. When he thought himself secure from his little enemies, he muttered to himself, "It served the little brat right for not minding me as he ought ter, when I told him to run to the house. I'll bet he'll go an' tell ma a lot of stuff, and then I'll ketch it. I wonder"—

"Hello there! what is the trouble?" said neighbor Green, who, hearing the cries of the child, and seeing a peculiar rustle in the bushes, had come to render assistance. Mr. Green is Sam's father, whom our little readers will remember as the one who showed Jimmy how to feed bees.

"W-h-o-t!" said Jimmy, who now ventured forth from his retreat. "Oh! nuthin'; I've been feedin' my bees—that's all."

"Did I not see you running, a moment ago?" said Mr. Green.

"Y-e-s; but I hain't 'fraid of no bees, only"—

"I understand," said Mr. Green. "By the looks of things I should say that the bees are robbing. See there! the cover of one of your hives is off. There is exactly where the trouble is. Evidently, by the way the bees act, that cover has been off all the morning. Cover the hive up immediately, and close the entrance."

Jimmy paid no attention, but commenced fighting the bees, as if that were the most important thing just then. Mr. Green, seeing that it was useless to tell him to do it, now clambered over the ricketty fence and fixed the colony. This done, he motioned Jimmy to stand back a little.

"Now," said he, "you or somebody else left off that cover."

"Why," replied Jimmy, when he had become more calm, "me an' Ted made some syrup last night. Well, one of my hives was weak, an' was black bees; so I thought I'd give 'em lots of feed. I poured the bread-pan clear up full, and before I could stop it the syrup run all over the enameled cloth and the outside of the hive. Well, I says to Ted, 'We'll leave the cover off that 'un, and put 'ton in the morning;' and"—

"You forgot it!" added Mr. Green, with a pleased smile.

"Well, 'twasn't *all* my fault. Ted he forgot it too," said Jimmy, not willing to bear all the blame.

"What did you leave the cover off for?" asked Mr. Green.

"Why, so the bees could crawl over the edge of the hive and lick it up."

"The syrup, I suppose you mean, and not the hive," said Mr. Green, with an amused look.

"Of course," said Jimmy, as if any one ought to know that.

"Now," said Mr. Green, as he was about to go, "I have closed the entrance and shall trust you to open it after a little. Don't forget it, for the bees will be likely to smother if left long."

When Mr. Green had gone, melancholy Jimmy began to brood over his feeding operation.

"Confound the bees!" he thought. "I wish they didn't have to be fed; an' why couldn't they act decent and not be a lot of crazy hogs? I 'most know Sam's pa will tell Sam that I run from the bees. My! I wouldn't have him know it for"—

"Jimmy! Jimmy! you come 'ere right away!" shouted a shrill, angry voice.

Jimmy obeyed very slowly; and when he had entered the house his step-mother began: "And w'at did ye let this child get stung for? Say, now; take that!" and his mother gave him a box on the ear.

This, together with the stings, irritated him, and he angrily replied:

"When I saw how cross the bees wus I told the little brat to go back; so now. He's always botherin' an' taggin' me round all over, an"—

"Not another word," said Jimmy's mother, gesturing with one hand. "I'll tell yer father to lick ye when he comes home, and he'll put an end to your bee-business. Mr. Brown has been for a long time wanting us to get rid of them bees, because he said they spoilt his fruit next to our line fence. No, sir; you needn't think you're going to feed them bees again."

Jimmy's heart was full, and he began to cry. He had hoped that he might make bees a success. So far they had cost nothing except for the little feed he had given them the night before.

The first swarm had alighted on a bush in the back yard, and Jimmy had managed to hive them in an old soap-box. Mr. Green, hearing of this, gave him three or four old cast-away L. hives. These he had not used for some years as he now used and preferred the chaff hive. He had an object in view in helping Jimmy. It was to win the boy to Sunday-school, in spite of the fact that his mother said he had "no good clothes." Poor Jimmy! His step-mother was unlearned, and overworked, and many times cross to her children. She loved Jimmy in her way, but did not and could not tell of the love of the Savior. The father was careless, good-natured, and what some folks call shiftless. A good deal of the time he was out of a job. Jimmy had never been taught of Christ, except now and then a word from Mr. Green, whom Jimmy admired.

The words of his mother he had just heard ruined all his fond hopes of becoming a bee-man like Mr. Green. He thought of how many happy hours he had spent with the bees; he had shown his boy-friends how well he could handle bees, and had boasted of what "piles of honey" he was going to get next year. To give up his bees now, seemed to him cruel.

While Jimmy was mourning thus over in the corner, his step-mother's tongue commenced again:

"I should think you'd be 'shamed of yourself. See how little Ted's eye is swelling, and how red it is."

While Jimmy was being scolded, Ted enjoyed it keenly, which, of course, did not just then make Jimmy feel very affectionate toward his brother.

"Jimmy," she said, at last, more mildly, "you go an' tell ole Aunt Julia to come over 'ere right away."

Jimmy obeyed; but on his way over there he said to himself, "She's nuthin' but an ole maid and an old quack, so she is. I just know she'll bring over all her old bottles. Sam's father said the best thing to do was to let stings alone, after you get the stings out."

As soon as Aunt Julia came over she began to pity Ted.

"Why, you dear little fellow," she said, sympathetically, "how swollen your eye is! how you must suffer!"

This was too much for Ted, and he began to cry as if he were really about to die.

"There, there!" said Aunt Julia; and she began to rub salt water on his eye. She then instructed Jimmy to mix up a little clay and water, and bring it in. He obeyed very reluctantly; and as he was getting it he said to himself, "It's just like her to tell me to mix up a mess of mud. I wish she'd got married."

If there was any class of persons whom Jimmy despised, it was "old maids," particularly Aunt Julia. After a little, Jimmy returned with the mud paste. This, "Auntie" (as she styled herself), much to Jimmy's disgust, plastered over Ted's eye. When she had fixed up Ted she proposed to Jimmy, that, as his eye and lip were swelling badly, he have the same treatment.

"I don't want your ole mud in my eye," stoutly persisted Jimmy.

"Jimmy," said his step-mother sternly, you let Aunt Julia poultice your eye."

Jimmy heroically obeyed, and went through the trying ordeal.

"If you're going to do that to every one of my stings, you'll have to plaster me all over," growled Jimmy, very indignantly.

"Auntie" paid no attention, but said, "There, now, I guess I have done all I can for you."

"Hump!" muttered Jimmy, again, to himself, as the mud trickled down his cheek. "I wonder why she don't dose us with her old medicine. All this kind of doctorin' don't amount to a hill of beans, 'cause Mr. Green said so."

"Jimmy, stop your mutterin'," said his step-mother.

"I didn't say nothin'," replied Jimmy.

"You said sumpin'," said Ted.

Aunt Julia prepared to go, leaving directions to bathe their faces in the morning with borax and water.

Soon after she had gone, Jimmy's father came home. Throwing his hat on the floor in the corner, he said,—

"Hello! what you been doin' with them young ones, Lucinda?" and then he began to laugh.

"I don't see any thing to laugh at," said she rather curtly. "This is all because that youngster over there has been feedin' his bees. He daubed my stove all up; and besides, as a result of his feedin' operations, both of 'em have been stung as you see. Aunt Julia has been over and poulticed their stings."

"I should think so," rejoined her husband, very much amused.

Ted now, to excite pity from his father, began to cry. The queer combination of mud and tears, as it trickled down his cheeks, did not call forth very much pity, but, on the contrary, considerable laughter from his father.

"Don't you remember," he said, after he quieted down, "that neighbor Green told us that all this fussing with stings never amounted to any thing? He said that tinkering, rubbing on salt water, and all that sort of thing only makes things worse."

Jimmy's mother made no reply; but it was quite evident that all her husband had said to the contrary had not altered her opinion one whit.

We will tell you more about Ted and Jimmy next month; but now we must give way for the juvenile letters. ERNEST.

BEES IN TEXAS.

Our bees gather honey from catclaw, mesquite, horsemint, and many other small plants. It is so warm that our bees are left on their summer stands all winter, and they never think of freezing. Papa's bees are mostly Italians. ADA MCPHAIL.

Gallinas, Texas.

THE HEDDON HIVE.

Papa likes the new Heddon hive, but he says your chaff hive would be better for bees so far north. Last year we got 2500 lbs. of extracted honey from 20 colonies. One swarm put in 65 lbs. in three days when basswood was in bloom. This year it was very dry, and pa thinks the frost killed the basswood-blossoms. We did not get much honey this summer. I like to work and go to school.

Mancelona, Mich. ENOIS SPRINGER.

I believe that Mr. Heddon does not claim that his new hive is adapted to outdoor wintering, but that as it is so light it can easily be carried into a cellar or other repository. Its lightness, together with the fact that its frames are fixed, so as not to shuck around, he says makes it comparatively easy to carry it to and from the cellar. For outdoor wintering there is nothing better than the chaff hive, or at least chaff packing of some sort. ERNEST.

HUBER, AND WHAT HE IS DOING.

We have had no cold weather yet this fall, but we are expecting it all the time. How is Huber now? He must be a big boy by this time.

Decorah, Ia., Oct. 30, 1886. ANNA BRICHNER.

Huber is getting to be quite a big fellow now, and he grows so fast that sometimes I think it can't be Huber any more. Lately he has taken a great liking to machinery, and especially to our new big engine. If you were to come here I think he would tell you all about how these big wheels go round. He likes to see the new machinery so well that we have been afraid he might get hurt, and so we have told him that he musn't go near the wheels except when his papa, his big brother Ernest, or his brother-in-law John goes with him. He and the engineer have big times together; and when it is time for our big steam-whistle to blow, if Huber happens to be around, the engineer lets him blow it, and my! he toots so loud that it is an actual fact you can hear him toot all over town. ERNEST.

A GOOD REPORT FROM MINNESOTA.

We had 32 swarms last spring. We have 52 swarms now; they are all nice Italians. We have extracted 250 gallons of honey, and have 600 lbs. of comb honey.

One colony, which did not send out a swarm, filled 42 one-pound sections and three boxes of frames. We never had such nice honey, nor so much. The season has been so dry that honey is so thick it is slow work to dip it. Our bees made much honey from red clover, which we thought extra, but it was not quite so white as from white clover, but very rich and nice.

Ma has made ginger cake of honey, but she likes sugar best. I will give you the recipe:

3 cups of honey; 1 cup of butter; 1 teaspoonful of soda; 1 teaspoonful of cinnamon; 1 tablespoonful of ginger.

I came very near having a swarm of my own this summer. I was feeding my chickens, and I heard a swarm over my head. I ran to call pa, who was putting hay in the barn; and when he got to the yard, expecting to find them settled, ready to hive, they had "gone west." Pa followed them a mile and a half, but they did not alight. LULU BISBEE.

Lyle, Mower Co., Minn., Oct. 15, 1886.

My experience is, that cakes made with honey instead of other sweetening are not as good, though I never saw the day when I didn't like honey-jumbles. ERNEST.

GLADDYS MAUD.

The following little piece of poetry Mabel has just laid on my desk. Who is Mabel? Why, don't you remember when she wrote a letter for GLEANINGS, telling about her papa's bees, about a year ago? Who is her papa? Why, he is Neighbor H., that great big "Uncle Hen," as the children all call him. He it was who furnished us so many and so nice queens for our trade last summer, after foul brood broke out in our own apiary. Who is Gladdys Maud? That blue-eyed little chick over across the way. The lines below describe her exactly, far better than I could if I should try.

COUSIN MABEL'S BABY-SISTER.

I have a little sister.
  Her name is Gladdys Maud;
But papa sometimes calls her
  His little "tiny fraud."

And this darling little sister
  Weighs all of eighteen pounds;
Her eyes are blue as violets,
  And her hair is short and brown.

This precious little girlie
  Is only six months old;
Although her hair's not curly,
  She's worth her weight in gold.

MABEL HARRINGTON, age 8.

There, now; don't you wish *you* had a blue-eyed sister like Gladdys Maud?

ERNEST.

CARNIOLANS THE CROSSEST BEES.

My papa has three kinds of bees—big brown, Italian, and Carniolans. The Carniolans are the crossest bees he has. Papa says that they are probably a cross between the albino and brown Germans; at least, he thinks that they must be hybrids of some sort. Papa thinks that you and Prof. Cook and some other wise men make some grand mistakes, such as bees producing wax by eating honey; bees gathering cotton and other fibrous matter to cap their brood; the queen changing the sex of her eggs at will; froth-bugs and leaf-hoppers, and your idea of a strain of queens that will not fight each other. Papa says he would not give a cent a thousand for such queens. SALLIE MORROW.

Wallaceburg, Ark., Oct. 6, 1886.

It seems to me, friend Sallie, your papa is a little hasty, is he not? Prof. Cook demonstrates pretty thoroughly, by experience and experiment, every thing he puts in print; and I do not think either of us write much from theory, but from actual practice and real work. Now, if your father is studying and experimenting, day after day and year after year, to bring out the truth, we shall be very glad to have an account of his experience.

KIND WORDS FROM OUR CUSTOMERS.

I received GLEANINGS, and am much pleased with it. I don't know how I managed to get along without it so long as I did. It is the best bee-journal published, I think. F. SOMERVILLE.
Monticello, N. Y., Oct. 29, 1886.

The 100 honey-tumblers came to hand in due time, and in perfect condition. I like them better than the glass honey-pails. They are a great deal stronger, and cost less. The freight was $1.10, the same as for 50 honey-pails. JOHN L. BONNAT.
Coulterville, Ill., Oct. 30, 1886.

Inclosed find N. Y. check for GLEANINGS. I have found that the money expended for GLEANINGS has been a profitable investment. I have become very much attached to it, and it can't come "any too often." Your A B C book is one of the finest I have ever seen. C. L. WHITAKER.
Hamilton, Ohio, Oct. 26, 1886.

The celery-plants I got of you are doing so well, and going so far beyond my expectations, that, for want of knowledge to carry them through, I inclose sixteen cents for the little book on the cultivation and winter care of celery. A. A. WEBBER.
Hinckley, Ohio, Oct. 20, 1886.

THE HOME READINGS.

My mother looks for GLEANINGS. She likes the Home readings. She is for ever telling me of what Mr. Root says of this thing and that, as if A. I. Root is always right. Never mind; continue putting your thoughts in print, for it helps others to live.
Shirleyville, Mass. W. E. GRIFFIN.

Inclosed please find one dollar. You may count me as a life subscriber to GLEANINGS. My little nephew, Walter Somerford, of Grimes Co., Tex., came to see me, and he had in his pocket the 15th of March No. of the above journal, and the first article I happened to read was headed "Our Homes." I read first to myself, and then re-read it to my mother, wife, father-in-law, and two little children.
Washington, Tex. JOHN M. DREW.

THE A B C BOOK, AND HOW EVERY THING BY ITS DIRECTIONS WORKS TO PERFECTION.

The goods were received, all in first-class order, for which I thank you very much. I have studied your A B C carefully, and we follow it just as nearly as we can, and every thing works to perfection. My bees are doing finely. From three wintered "skeps" we had eight swarms. Our blacks are somewhat cross to hive, but the Italians are like kittens. I nearly drowned one swarm of blacks before they would give up, but now they are well-to-do people.
MRS. CHAS. MCDONALD.
Centreville, Sullivan Co., N. Y., July 9, 1886.

"NEVER HAVE HANDLED SO PERFECT A LOT OF STUFF."

The goods you sent me were received. Though I have worked a great deal of material in my life, I must say I have never handled so perfect a lot of stuff as that was. Should I need more another season, I shall send you my order. I am glad to know you are selling so much hive-material after your misfortune by the fire. My bees are doing better than ever before. I allowed them to increase from 28 to 56 colonies, mostly by natural swarming. I had one swarm only that went to the woods.
Oriedo, Orange Co., Fla. J. S. WAMBLE.

HOW OUR GOODS TAKE IN CALIFORNIA.

I have been very busy all summer, and have reaped a pretty good harvest of honey—about 3000 lbs. from 40 hives; or, if they had *all* been Simplicity, I think I should have had 1000 lbs. more. Well, so far so good. Those little white sections of yours beat every thing there is on this coast, as you will take notice from a letter in the Reno *Journal*, from the Mechanics' Fair held in San Francisco, in September, 1886. Our honey here is very white and clear, and free from any foreign flavor, and is mostly from alfalfa and white clover. Your Simplicity took the premium at our State Fair, as also did Novice's extractor, and *I* also came in for the premium on honey for the best display of sections, extracted, and the best box, and a recommendation for another premium, so you must think that I feel very much pleased with my honey-crop this season.
Reno, Nevada, Oct. 18, 1886. E. A. MOORE.

THE SIMPLICITY BEE-HIVE; FOUNDATION-MILLS, ETC., AT THE FAIR.

The fair has come and passed. The foundation-machine came just in time (the first day of the fair), and was placed on exhibition, and attracted a great deal of attention, being the first on exhibition in Western Washington. I sold all the A B C books you sent me, and I got the first premium on Simplicity bee-hives. I was successful in carrying off the prize for the best "native honey in the comb." Of course, I had some of my best section honey in competition with comb honey placed on glass, and many were the remarks made in favor of the *new* method over the *old*. I took great pleasure as well as pains, in showing the people the advantages of the Simplicity hives, and the manner of manipulation of the frames, sections, and comb foundation; also I had a second story with honey stored in sections just as they filled them. "And will the bees fill them like that?" was heard a great many times.

This has been a very unfavorable season here for bees to store honey, as there have been scarcely any flowers since the white clover season closed, which was short, on account of dry weather. I transferred all my bees this year into Simplicity hives, except one which I bought in a Simplicity hive, and from it I obtained 65 lbs. of section honey; and from some which I transferred, I got 15 to 20 lbs.; and from the rest (far the greater number) I got nothing, but will have to feed several to keep them from starving before spring. I am well pleased with every thing you sent. My good wife says the Hunter sifter is just capital, and doesn't see how she ever got along without it before. She likes to hear me read the story of Jane Meek & Brother. She says that sounds so much like "woman's rights." T. L. HOLLOWAY.
Chehalis, Wash. Ter., Oct. 9, 1886.

A KIND WORD INDEED.

Dear Friend Root:—I want to talk to you awhile, not for publication, but to yourself, out of appreciation for your good influence in my home through GLEANINGS. I never saw you, but you are a near "heart-acquaintance." I want to tell you, that last July, a year ago, I followed Ernest's and Maud's examples and "swarmed out," and secured, in Southern Kansas, a South-Eastern Ohio girl; and being from near Dayton myself, my queen and I shall claim a relationship with you, anyway. My queen is a devoted Methodist, which will be pleasing to you, and has read the Bible nightly, and led family worship every since we were married. I have been brought back very near, if not right to the foot of the cross through her influence, and I know she won't stop till she is satisfied I am planted firmly on the solid rock of Christ. The good part is to come. On the 2d of Sept., in New Orleans, she gave birth to a fine daughter, which we have named after that great and good woman, Frances Willard, which name is a sufficient exposition of our principles. We feel we have secured a gift from God, and shall try to bring it up in a Christian home. When my wife joins me again I shall take my place at the family altar and do my duty. You have shown us very much in your Home Papers how to draw near to God, how to secure the simpleness of heart so necessary to perfect Christian love. C. M. HIGGINS.
Hahnville, La., Sept. 22, 1886.

[Our readers will notice that the above is not for publication. I have, however, obtained permission from the writer to use the letter as I thought proper; and when I wrote him I earnestly entreatly him to take up the cross and lead in family worship himself in his own home, as he proposes. After the letter was gone I prayed that God might bless my feeble words. I am happy to tell you he has just written me of his complete surrender, and of the establishment of the family altar.]

OUR HOMES.

Let nothing be done through strife or vain-glory; but in lowliness of mind let each esteem other better than themselves.—PHIL. 2:3.

FOR some time I have been considering this matter of awards at our fairs and honey-shows; and I have been pained repeatedly to hear of hard feelings because of the way in which awards have been made. I have, at different times, been one of the judges at fairs, and also have been several times exhibitor. I have been awarded the first premium, and at different times the second premium; and I believe I have also made exhibits when I received no premium at all. As our fairs and expositions are, without question, a wonderful means of educating the people, it seems extremely desirable that we should try to get over or do away with any thing that hinders their usefulness. The Centennial Exposition tried to meet the matter by awarding no first premiums to anybody—simply giving awards to every thing meritorious. It did not seem to answer the purpose, however, if I am correct; and I do not know of any better way than to give first and second premiums, as most of our fairs now manage it. How, then, shall we avoid hard feelings, and the fierce jealousies that now and then spring up and make those who have been good friends estranged, sometimes, may be, for life? The following letter states the case so thoroughly I give it here entire, omitting names and addresses:

A. I. Root, Medina, O.:

Dear Sir:—I wish your decision as to the following: *Mr. A* exhibits one wax-extractor, one bee-veil, one bee-feeder, one queen-nursery, one hook to lift frames, and one honey-knife—6 articles, and he is awarded the first premium, or $10.00, for the *largest* and *best* display of apiarian implements. Mr. B exhibits one swarming and transferring box; one queen and drone catcher (Alley's); 7 bee-brushes; one bee-smoker; one hive-ventilator; one bee-feeder; 80 bee-hives in flat; 60 zinc honey-boards; one tool to make wire hooks in frames; one tool to put fdn. in frames; tweezers to catch queen and bees for caging; one wire-nippers; hammers, all sizes; tacks and nails; brace and bits for boring frames; screws and screw-driver; the A B C book, GLEANINGS and *A. B. J.*, and yet he received the second premium, or $5.00. Mr. A told the examining committee privately that the tools put in by Mr. B were not apiarian tools, as I learned from the superintendent afterward, and the superintendent told the committee he thought they were deciding wrong. Mr. A first (after protest was made) agreed to leave it to you to decide, but later he backed out as to that, and would do nothing but hold all he had got by the award. Is Mr. B warranted in letting Mr. A severely alone in the future, for his grasping selfishness in claiming what he is so unjustly entitled to? At the examination of bees for award on best colony, Mr. B told the committee he conceded the first to Mr. A, and extpeced the same courtesy in return on tools, as it was so apparent. J. L. D.

Probably many of our readers will recall to mind having had experiences quite similar to the above, especially if they are the class of people who attend fairs, and make exhibits. A and B are both good men—at least, so I take it. The judges and superintendent are good men; in fact, I think that bad men seldom get into such places; that is, the judges are usually selected from those whose general tenor of life indicates that they wish to be fair and honest, and, as a rule, free from prejudice or partiality. When I say that A and B are good men, I recognize that they are human, like you and me, and are liable at any moment to be tempted by the evil one, so that their ordinarily good judgment and keen perception may be impaired. I think I told you, years ago, that I decided, even before I became a Christian, it was wrong for *me* to play checkers, because I was sure to become too much excited by the game to feel charitable or kind toward my opponent. It used to be the same with me when I went to spelling-school, when we were allowed to "go up" in the class. Well, our county and State fairs are very apt to encourage this feeling of rivalry and jealousy—a good deal more so than checkers and spelling-schools, because our *money* is involved, and frequently, also, our opportunities for increasing our business. Shall we, then, stay away? If there were not enough good at our fairs to overbalance the evil, I would say, stay away; as it is, I think it our duty to go. But when we go, let us learn to be *men* and *women*, and cultivate the spirit of the little text I have placed at the head of our chapter. Notice, dear reader, the wonderful beauty of the words of that kind-hearted veteran, Paul. One recognizes at a glance that Paul had his conflicts, and knew how it was himself. "Let nothing be done through strife or vain-glory." One is almost tempted to think that Paul had in his mind the matter we have been discussing, when he uttered the words. And, again, "But in lowliness of mind let each esteem other better than themselves." How completely these words meet the case in question! and did we but heed them and obey them, how fully should we be delivered from all strife and unpleasantness!

Our good friend A without a doubt felt a little spiteful toward B because B had brought out a larger and finer exhibit. Now please have charity for friend A, dear friends, and don't be too severe on others like him, who are now and then tempted to do things they would never think of unless under the pressure of something a little unusual. I can imagine A looking over at his neighbor, and catching a glimpse of those tweezers to catch queens with; also the show of hammers of different sizes. Poor A! Satan suggests to him, "Look here, old fellow: If you had brought hammers and nails, screw-drivers, and all the pincers and nippers there were about the house, you might have made a big display also. Now, I think it is your duty to quietly suggest to the examining committee, that, although these things are very fine, they are not, all of them, implements for bee culture." Why, don't you see, dear friends, the matter could be put in such a way as to make it appear that B had pretty good grounds for his suggestion to the judges? The judges, not being very well posted in regard to bee-implements, may have concluded there was reason and justice in the suggestion. Their proper way would have been, however, to interview B, and ask him if he considered hammers and screw-drivers, strictly speaking, implements for bee culture; then each party could have defended his position. Of course, the judges would have to decide one way or the other, eventually, for the question is like thousands of others that come up —one that can not be settled definitely, but must remain, for all time to come, matters of opinion, and on which good people may honestly differ. The superintendent, desiring to be fair about the matter, tells friend B why his larger exhibit was given only the second premium. At this, friend B is terribly stirred up. I feel exceedingly grateful to him for the compliment that he pays me in suggesting that *I* should decide the matter; but I hope he will not feel hard toward me when I say there is no way of deciding it, that I know of, that will begin to compare with the one suggested by our text. I should say, "Now, good friend B, as the decision has been given by the judges, by all means drop the matter and let it rest there. May be you can not help feeling hard a little; but, dear friend, please try to think that what is your loss is your neighbor's gain, and that it does not matter very much after all who has the money or who has the honor and the glory in this world. Make up your mind to be manly and liberal about it, no matter if it does look unfair and underhanded. A is your neighbor; and if he has shown a greedy and selfish disposition, try to feel truly and really sorry for him, just as you would if he were your own flesh-and-blood brother. By *no manner of means* think of letting him 'severely alone,' as you term it. He is not a bad man; in fact, I think I am right in thinking you have always heretofore held him in high esteem. Hold him in high esteem *still*, dear brother; pass it by, and let it go. 'Let this mind be in you which was also in Christ Jesus;' 'but he made himself of no reputation, and took upon him the form of a servant, and was made in the likeness of men: and being in fashion as a man, humbled himself, and became obedient unto death, even the death of the cross.'" I have been through these trials, dear brother. I have cherished unkind and ungenerous feelings toward the one who took the premium from me; and I have again, on the other hand, said to myself, when I felt the promptings of the tempter, "Get thee behind me, Satan."

I have oftentimes of late been tempted to think uncharitableness the most comprehensive and most common sin to be found in the world. If we cherish unkind and uncharitable thoughts toward a fellow-being, nobody knows what the end may be. If these thoughts are not put away and stilled, they may result even in murder; and who shall fathom the agony and remorse one who has committed such a crime is compelled to carry through life? I do not know what this awful remorse is; but I do know of the wonderful and untold blessings that flow into the heart, and, I think I may say truly, into the *purse*, of him who tries to obey the command of our little text. I remember the time when there was a little strife in our town, about who should have a certain kind of work. I do not like to be beaten in *any* thing; and before I knew it, I was planning to get the work away from my competitors. Thank God, however, the influence of Christ's spirit began to strive with me; and finally I told the one who had it in his power to let out the work, I would rather he would give it to the other parties. He seemed a little surprised until I explained to him that they, perhaps, needed the work more than I did; and as there had been some feeling in the matter already, I would let go what advantage I might derive in getting it myself, and finally told him I should feel happy in letting them have it, and I did not tell an untruth, dear friends. There came a feeling into my heart right away, that the little sacrifice I had made was laying up treasures in heaven, if not here on earth. I have experienced this feeling many times, after triumphing over selfish feelings and jealousy; and, strange to tell, it seems as if I had not lost any money by it either. A great many times it is a hard matter for judges to decide in regard to the comparative merits of exhibits; and, again, they sometimes look at it somewhat in this way:

One man of considerable wealth and means makes a large exhibit; in fact, he excels in almost every thing. Another competitor, however, a man of limited means, has a small exhibit, but has every thing very nice. He has certainly done wonderfully well for one with so few advantages and with so little means. Shall *all* the premiums be given to the man who has so much? This, too, may be a question that all would not agree on. One of the judges may say, "It is our duty to make the awards without regard to the condition or circumstances of the competitors; in fact, we ought to make them as if we did not know the parties at all." Another might say, "But *I* think, friends, that it does make a difference who the man is. The one who has accomplished a great deal with very small capital and advantages ought to be rewarded." A third one may say, "I tell you, my friends, what *I* think about it. I do not believe it is a good thing to give all the best premiums to one man. The premiums are offered with the view of encouraging agricultural industry, and let us divide them around a little, giving each one something, to encourage him for the time and trouble and pains he has taken." I might go on and give other similar examples; but all I wish to show is, that the judges may be good men, and actuated by the best of motives in making awards that sometimes seem to us singular and uncalled for. Now, is it not a great deal better to try hard to take a charitable view of all these things? Search diligently for good motives instead of evil ones, when you feel like criticising. To come back to our text, "In lowliness of mind let each esteem other better than themselves." You do not believe *you* are actuated by narrow and selfish motives; then be generous enough to think at once that others are like yourself.

It cramps and warps and deforms a man to get into the habit of thinking everybody unscrupulous and unprincipled and greedy. Try to be liberal-minded; try to be whole-hearted; try to be generous; don't stop and pick and quibble about little things. Let it pass—let it pass, thinking that what is your loss is another's gain, and that, may be, it will do him more good than it would you.

And now a word in regard to that part of the letter which suggests letting the individual severely alone. My friend, this "letting alone" very often amounts to striking him a blow. I do not see how a Christian can possibly be excused for so doing, for the Master says, "Love ye your enemies; do good to those that hate you." Now, you can not do good to a man by letting him "severely alone." It may not always be best to speak to him, or to have very much to do with him under certain circumstances; but it is the duty of a Christian to be always striving to do good wherever an opportunity offers; and the letting-alone principle generally includes refusing to do him a kindness when opportunity offers. Now, if we are going to do good to our enemies as well as to our friends, we come pretty near promising to do good to everybody, irrespective of what has heretofore happened. If you have never tried it, suppose you surprise some one by doing some little friendly act for him, even after you two have had difficulties. Surprise him by letting him see that you have concluded not to treasure up or remember it against him. My friends, we have not time to indulge in hard feelings toward *anybody.* Some of the best lessons in this line I ever got in my life were from our good friend Prof. Cook. The good lessons were not in the way of advice, but they were in the way of actual experience and transactions. Sometimes I wonder how it is, and what is the secret of the great hold he has on the hearts of the people—not only the people of Michigan, but people everywhere he is known, either through personal acquaintance or through his writings. I think I have found the secret. What do you suppose it is? Why, it is embodied in the little text at the head of this talk, better than any words I can frame to tell it. The way is open for you to go and do likewise. There is no patent right on loving your enemies, and doing good to those who hate you. There is no patent right against putting away strife and selfishness. Christ's teachings are free to all. The saddest part of it is, that so few are found to take advantage of them, thus making not only this world pleasant, but laying up treasures in heaven by means of these same teachings.

It seems to me that Satan sometimes warps our better judgment in these matters by persuading us that it is our duty to bring the guilty to justice; and the evil one may even persuade some usually well-meaning man that he is doing God service in prolonging a useless quarrel and controversy. There are many texts in the Bible, commanding us to give way and to suffer wrong, and to judge not; but there are very, very few enjoining us to expose a brother, and bring his iniquity to light, even when he is doing wrong. Would it not seem, in view of this, that the tendency of humanity is much oftener toward the one extreme than to the other?—that is, difficulties among friends and neighbors are very rarely of such a character as to demand lawsuits or public exposure. Even in this great trouble that is before our people now about the intemperance of our land, I believe we often err in being in too great haste to condemn too severely. No doubt, something ought to be done in all these cases; but the question seems to be, What is the wisest thing to do? If we stop and ask ourselves what course will do the friend in question most good, we shall seldom be led astray.

A few days ago, one of the book-keepers submitted a letter to me that she had written to a man who had behaved very badly. I told her it was too severe.

"But, Mr. Root, it is the exact truth," said she.

"I know it is, but I would not tell the exact truth." She looked at me a little inquiringly.

Now, friends if the erring one were one of your own family, and you were telling what he had done that was wrong, would you tell the whole truth? I think not. You would soften it and omit unnecessary details, and I think you would be doing right. Evil is bad enough without exaggerating it and giving the full details as the sensational newspapers do. Well, now, if you will soften it and put it mildly because the offender is a relation, why not consider all mankind related to you through God the Father, and appeal to his better feelings, if possible, by stating his offense so mildly that he will recognize you do not put it as bad as it is. It is a very hard thing to do this when you are excited and stirred up; but I tell you, my friends, it is a wonderful thing to be able to control your feelings so as to hold back even *truths* which it would be better not to utter, or that are not necessary to be told. A good friend of mine once suggested to me that I should remonstrate with one who was acting very provokingly. I replied that I had decided to do so a dozen times, but that, when I began to consider the matter, I felt that I should say too much, and so I said nothing. The reply was, "I think, Mr. Root, if you only had grace to do it, it would come better from you than from anybody else."

I have often thought of that word "grace" —the grace to reprove, and yet do it mildly, kindly, and lovingly. How beautiful and lovable is this trait when we see it in others! May God give us that coveted grace, even though it seems as if we have not inherited it by nature; and may he help us, that nothing be done through strife or vain-glory. May his Spirit sustain us and help us, in lowliness of mind to esteem others better than ourselves.

Now, a word more, in regard to this matter of not telling the whole truth when you are discussing some trouble with an opponent. Both of you are excited, and greatly disposed, when speaking to each other, to state it a little stronger than the real facts in the case will warrant. Recognizing this, be sure that all of your statements are a little below the mark, as it seems to you. Your opponent is watching keenly for any evidence of insincerity or untruthfulness on your part. He may be a bad man himself, and therefore he is hoping to find you are equally bad, and is ready, at the smallest excuse or provocation, to call you untruthful. Be guarded and wary. Surprise and disarm your opponent by statements so mild that he will be forced to say in his heart, "Well, I declare! the fellow is fair, even if he is right against me in this matter." He may have been ready to call you a *liar* the minute he catches hold of the very smallest exaggerated statement. Make every point and every complaint of his conduct a good way inside of the line of truth, and then you are on the safe side, anyway. We unconsciously measure each other, and just bear in mind with what respect and reverence you look up to a man whom everybody knows is mild and fair, and within the bounds of truth in all his statements. Don't let the heat of controversy, or any temptations in the way of selfishness, lead you to overstate. Be kind, even to the unthankful. The power and influence and weight of a man who is universally known to be kind and fair, even when he has been misused, is wonderful; and even bad and wicked men look up to him with reverence and respect. Shall we not strive for such a reputation among men?

Our Own Apiary.

CONDUCTED BY ERNEST R. ROOT.

FEEDING, AND THE BEST FEEDERS FOR BUSINESS.

In talking now upon feeders and their relative merits, I hope I may not be understood as saying that the feeders which I shall recommend are the best, but, in my opinion, are the best we have *tried*, for reasons which I shall presently give.

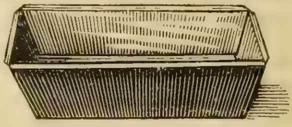
I believe that, in answer to a correspondent recently, I stated that we used and preferred the bread-pan feeder. So we did at that time; but a combination of circumstances has reversed my opinion. It occurred something in this way: About the time we were placing bread-pan feeders upon the hives, preparatory to feeding, our supply of feeders gave out.

"Can't you find any more bread-pans?" said I to the apiarist.

"No," he replied; "but there are some old trough Simplicity feeders in the second story of the house-apiary; but, one of those won't hold enough for feeding up quick."

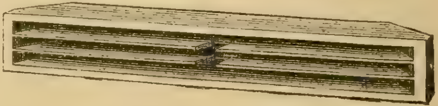
"Well," said I, "if there are enough we will give each colony three, which number, I think, will hold about the same quantity of syrup as one of the bread-pans."

We managed to scrape together about a hundred. To every colony that still lacked a bread-pan we gave three of these Simplicity feeders, placing them on top of the enameled cloth, the latter being turned back so as to allow the bees to come up and "drink." The bread-pans, with a piece of cheese-cloth, were laid upon the enameled cloth in the same manner, there being only one to each hive. The feeders were filled at night, as I have before explained in the previous number. We had not continued our feeding more than a day or so before our preference was decidedly in favor of the Simplicity feeders, for these reasons :



BREAD-PAN FEEDER.

The cheese-cloths in the bread-pans, after they are empty, in the majority of cases stick to the bottom of the pans, and it is no little task to pull them up; 2. The cloths have always to be pulled away before filling, which takes time; 3. The sides of the pan being made of tin, and sloping at that, makes it no easy matter for the bees to get at the feed; 4. If the cloth is not laid over the pan of syrup very carefully, a good many bees are apt to get drowned; 5. In cool weather the bees will scarcely ever take feed from them—from the fact, I suppose, that the metal is cold to their feet. None of these objections can be named against the Simplicity feeder. With the latter it is only necessary to raise the cover and pour in the syrup—no cheese-cloth nor any thing of the sort to fuss with. If the three feeders are full of bees it is of no consequence; pour the feed in just the same. The bees that are immersed in the syrup will crawl up the partitions in the feeders, as it were, and none will be drowned—at least, I have never seen any dead bees in the Simplicity feeders, and I have tried to so besmear the bees with syrup as to drown them. Perhaps some of our A B C scholars would like to see a cut of the Simplicity feeder, showing the partitions, which prevent the bees from drowning.



SIMPLICITY FEEDER.

It is simply a wooden trough; and the fact that it is made of wood, constitutes one of its chief points of excellence. The wood is a non-conductor of heat and cold, and during cool weather is not so apt to repel the bees. Its wooden surface also renders it an easy matter for the bees to gain access to the feed, and the rough sides of the partitions, as left by the wabbling-saw, serve as an excellent foothold to the bees in climbing, even when besmeared with syrup. A bee that can't climb up these partitions is no bee at all, and ought to drown.

The fact that the Simplicity requires no floats or cloths to be lifted out and replaced, makes it possible to feed up a lot of colonies in nearly half the time that the bread-pan feeder requires. It not only takes less time to fill the feeders with syrup, but the bees will in every instance show their preference by emptying the Simplicity first. In perhaps a score of hives, we placed, on top of the enameled cloth of each, three Simplicities and one bread-pan. In every instance the wooden feeders were emptied long before bread-pans. If any of my readers are skeptical, let them try the same experiments and note the difference. I think your verdict will be that you will want no feeders except those made of wood.

Some one says, "The Simplicity is too small." It is just right for stimulating brood-rearing. When it is desirable to feed, say 10 lbs. of syrup at a time, I place ten of the Simplicities right on top of the frames, side by side, leaving a bee-space between each feeder. Over this I place a couple of Hill devices, and lay the enameled cloth over the whole. But it is not often that we need to feed that quantity at one time. That the bread-pan is a good feeder, and will do good work, I do not deny; but I only claim that the wooden feeder is much superior.

FEEDING IN COOL OR FROSTY WEATHER.

While we were feeding, a cool spell of weather with frosty nights came upon us, and the bees seemed loath to take down the feed as usual. As they had not then quite sufficient stores for winter, I did not wish to have our feeding prevented because of a little cool weather. It occurred to me, that if we should put the feeders directly upon the frames and cover with a chaff cushion, the feed would be stored in the combs as before. As the Hill device would have to come into requisition soon, it would be just the thing to keep the cushion from sagging into the syrup or prevent it from so covering the feeders as to exclude the bees from the feed. We accordingly put chaff cushions on all the hives, and arranged the feeders as I have indicated; i. e., with a Hill device spanning the feeder, a sheet of burlap covering the whole, and, last of all, the chaff cushion to keep in the warmth. The effect was all I could desire, and the bees carried down the feed as in warm weather. If the weather was too cold they would empty only the Simplicity feeders, and the bread-pans remained untouched. In view of these facts I do not think we bee-keepers want any feeders made of metal, but of wood, and of the simplest construction.

MAKING SUGAR SYRUP BY STEAM.

We have worked up six or seven barrels of granulated sugar into syrup for winter stores, by the use of steam. Perhaps some of our readers might be interested as to our manner of making it. A barrel of sugar is taken down into the "wax-room," as we call it, and unheaded at a convenient distance from a large extractor-can. In this the syrup is made. The can is mounted on a box of the proper height, both for convenience in working as well as for drawing off the syrup from the honey-gate into a suitable receptacle. Closely adjoining is a steam-pipe to which is attached a rubber hose, the latter reaching into the extractor-can; at the left of the steam-pipe is a water-pipe. With a long wooden paddle and a tin pail, every thing is in readiness for making the syrup.

Our proportion of water to sugar for mixing is a gallon of the former to 25 lbs. of the latter. If the syrup is to be made on a stove, our proportion is a gallon of water to 20 lbs. of sugar. When heating the syrup by steam we have to allow a little for the condensation of steam. To get the proportions right, we first weigh a pail of sugar, and then after that simply measure the sugar by the pailful. Now, we do not mix the sugar and water all at once, and then apply steam, but we put just enough water in our extractor-can so that, when the proportional amount of sugar has been added by degrees, the can will be full of syrup. By the application of a little arithmetic we can determine how much water to put in the can so as to come out right. We will suppose, then, that we have poured in the requisite quantity of water. Turn on the steam and let the water snap until about the boiling-point; then scoop up a pailful of sugar, and with one hand, pour it on the hot water gradually, and with the other one stir with the paddle I have mentioned. Continue stirring until the sugar is all dissolved, and the syrup looks transparent. In like manner pour in the second pailful, stirring as before, and so on until the proportional numbers of pailsful are exhausted. If your calculations have been right, and you have followed directions, your can will be full of beautiful clear syrup. There ought not then to be any granulation, though there may form a little scum on the surface of the syrup. The bee-feed is now hot, and will have to remain eight or ten hours to be cool enough to feed.

You will perceive that there is not a particle of danger of burning the syrup when heated by steam; and after the sugar is in we generally let it boil for 10 or 15 minutes, to make sure that it is all dissolved. While stirring, occasionally run the paddle through the gutter that leads to the honey-gate, for oftentimes it may become clogged.

Now, perhaps some of our readers may think that, in making syrup, we go through a good many unnecessary operations. Possibly we do; at any rate, for the last four or five years this is the syrup that we have fed to the bees, and our success in wintering during this time has been good, as our readers are aware. Whether the syrup has any of the credit, I would not say; but I believe it has been one of the important factors.

HOW TO GET RID OF LIFE-INSURANCE AGENTS, OR ANY OTHER KIND OF AGENTS.

One warm day, after the colonies had all been fed up, I was engaged in packing the colonies in chaff. Wishing to take advantage of the warm weather as long as it lasted, I was desirous of getting all the colonies packed before the cold set in, and consequently was quite busy. While I was thus occupied I saw a familiar form advance toward me through the aisles of the apiary. Yes, it was the life-insurance agent. As I am a young married man, he was very desirous that I should take a policy in his company. While he was explaining the "semi-tontine" plan and its advantages, and was about to press his argument, I saw that I was being hindered. A bright thought struck me. Was I going to take out a policy? "Oh, no!" I said to myself. "Here is a hybrid colony; I will accidentally (?) bump the hive. I can easily stand a couple of stings."

While this thought was passing my mind, and I was about to execute my plan, I am sure I looked pleased. My companion, thinking that I was about to tell him I would take out a policy, advanced nearer to me—just what I wanted.

"My! these bees are cross fellows," said I.

My companion took the hint; and as he started off on a kind of dog-trot (he weighs 200) he said, "Good-evening; will see you at another time."

GLEANINGS IN BEE CULTURE.
Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, O.

TERMS: $1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, NOV. 15, 1886.

Do all things without murmurings and disputings.—PHIL. 2:14.

WE will give 15 c. each for May, 1875, GLEANINGS.

ERRATUM.

IN the last column on page 900, in this issue, the reference should have been to GLEANINGS for 1885, and not to the "Winter Care of Horses and Cattle."

FRIEND HUTCHINSON'S LOSS BY FIRE.

THE following is from friend W. Z. H. by postal:

> We have lost nearly 1000 lbs. of our choicest comb honey, by the burning, last night, of our railroad depot, where the honey was stored preparatory to shipping. The postoffice, hotel, and a store were also burned. W. Z. HUTCHINSON.

THE BUSY BEE.

FROM Rev. E. T. Abbott, St. Joseph, Mo., we have received a little work on bees, entitled, "The Busy Bee; or, Bee-Keeping in a Nut-shell." It is in pamphlet form, and contains 40 pages of matter, of which something over half is devoted to bees, and the rest to advertising. It can be obtained from the address above. Price 15 cts.

DISCOUNTS FOR THE MONTH OF DECEMBER.

UNTIL Dec. 1 we will allow 8 per cent discount on all goods which, from their nature, can not well be used until next season, as given in our last issue. During the month of December the discount will be reduced to 5 per cent; in January it will be 4 per cent; in February, 3 per cent, and in March 2 per cent. After April 1, net cash as usual.

COMB HONEY IN GLASSED SECTIONS, AT ONLY 10½ CTS. PER LB.

IN order to close out the lot mentioned on page 329, April 15, we will sell it in lots of 10 cases at 10½ cts. per lb.; less than 10 cases, 11 cts. per lb. This is nice honey, and can hardly fail to give satisfaction. The only objection to it, that we know of, is, there is a sheet of glass fastened on each side of a section, and, of course, this glass is weighed up with the honey. See description on page referred to above.

LETTUCE IN THE OPEN AIR, IN THE MIDDLE OF NOVEMBER.

WE have this morning pushed away the snow from off the heads of Tennis Ball and "Deacon" lettuce, and gathered a basketful of about as fine heads as any we ever saw, although not quite so large in size as those raised in summer. I hardly need add, that it was grown over the New Agriculture. The mercury has been several times down to 20 degrees—12 below freezing—but it does not seem to hurt it a particle. Before it gets much colder we shall cover it with sash or oiled cotton cloth, nights, or when it freezes severely during the day time. We are going to have a fine lot of it ready for Thanksgiving. The "Deacon" is a new variety that promises to be an acquisition. The leaves are smooth, flat, and round. It is an enormous grower, and the heads are very handsome.

REPORT OF THE PROCEEDINGS OF THE INDIANAPOLIS CONVENTION.

THE above report is very neatly gotten up. It is a book closely written, of 32 pages. It is furnished by the *American Bee Journal* for 25 cts. It seems to me the matter contained in it ought to be worth that to any enthusiastic bee-keeper. While I am about it, I believe I omitted to make editorial mention of the proceedings a year ago. I regret this, as it embodied also a history of the N. A. B. K. S. from 1870 to 1884. The price is also 25 cts., furnished by the *A. B. J.* This latter book contains 64 pages. While we are looking over these convention reports, I feel moved to say that the editor of the *A. B. J.* should receive a vote of thanks for the very faithful service he has rendered at different times to this convention, or, so far as I know, at *all* conventions. He is a most excellent reader and speaker, full of good-natured pleasantry and enthusiasm; and with the experience of the last two or three conventions before me, I for one should feel sorry to find friend Newman absent from any convention I might have the good fortune to be permitted to attend.

A GOOD TELESCOPE FOR A SMALL AMOUNT OF MONEY.

WHEN I was a boy I was greatly taken up with a description of a home-made telescope, described by the great astronomer Thomas Dick. The glasses were good, but the tubes were made of pasteboard formed by rolling up old newspapers. They can be made so as to slide one into the other, and answer every purpose of the expensive brass tubes, only when you draw the instrument out the tubes may come clear out and pull apart if you are not careful. Well, we have just succeeded in getting a lot of telescopes made in this way. The power is pretty nearly equal to our $2.00 brass telescopes, but the price is only 50 cts. Or we will send it for 2 new names or 4 renewals. They can be sent safely by mail for 6 cts. extra. When drawn out the instrument is 36 inches long; but it shuts up to 11½ inches. The paper tubes are nicely finished and varnished, and the ends are capped with brass, so the instrument is not bad looking after all. We are so confident that these will please the juveniles who have a love for telescopes and astronomy that we will take any one back that does not give satisfaction—you, of course, paying postage both ways. They are made to be used as a marine telescope. We hope to have a picture of the instrument in our next issue.

AN AGENT FOR GLEANINGS AT EVERY POSTOFFICE.

A FEW weeks ago I suggested that somebody at every postoffice take the matter in hand, of visiting all the bee-keepers, with a view of getting them to subscribe to GLEANINGS, and that that person should have 25 cts. for each name he sent in *from his own* postoffice. The question arises, Shall the one who acts as agent for GLEANINGS receive 25 cts. for sending in his *own* name? To be sure, he may; but before giving him this wholesale rate, we wish him to call on all the bee-keepers near him, as mentioned above. If he does not succeed in getting *even one name*, he may still have GLEANINGS for 75 cts., providing he sends us the names of those upon whom he has called. We want these names to make up our list of those to whom we send price lists once or twice a year. Now, we hope there will be no rivalry in this matter. Let the bee-keepers at each postoffice decide upon some one among their number to receive subscriptions. As I said before, the supply-dealer of the neighborhood would be the proper party, generally speaking. I do not know how we can permit you to take names from other postoffices than your own. This would virtually amount to cutting down the price of GLEANINGS, and I think it better that each agent should get a full dollar from each subscriber. Be sure you state, when you send in names to take advantage of this, that *you* are to be agent at your postoffice.

A BARGAIN IN WATCHES; ALSO, HOW TO GET A WATCH FREE.

WE are now selling our 23d gross of Waterbury watches. The latest style is series E, which we send postpaid and registered for $2.75. We have on hand a few of the old styles, which are as good timers as the late styles. We should like to close out these old styles, and, in order to do so, we make the following low prices on these watches, regulated and tested to run in the pocket:

Series C, postpaid,............................ .. $2 50
" B " 2.00
" A " 1.50

Who ever heard of a watch that would keep good time, for such an insignificant sum? and if you haven't the money to send, I'll tell you another way to get them:

To the person sending 5 new subscriptions to GLEANINGS, at $1.00 each, we will send a new "Series E" watch, postpaid, free; for 4 new subscriptions, a "Series C" watch; for 3 new subscriptions and one renewal, a "Series B" watch; and for 2 new subscriptions, and 2 renewals, a "Series A" watch. Where is the girl or boy who can not, with a little effort, induce his bee-keeping neighbors to take GLEANINGS, and thus get a watch free? As our supply of these old watches is limited, you will have to go to work at once, or they are likely to be all gone.

CONVENTION NOTICES.

Nebraska bee-keepers will meet for their next annual session in Lincoln, Neb., on the second Wednesday in Jan., 1887.
H. N. PATTERSON, Sec.

THE MICHIGAN STATE BEE-KEEPERS' ASSOCIATION.

The executive committee for the above association are at work getting every thing ready for their next annual meeting, Dec. 1 and 2, 1886. A large and varied programme is being prepared. Several excellent papers have been promised. The meeting will be in Grange Hall, in Union Block, with headquarters at the Hawking House, where reduced rates have been secured. Ypsilanti offers many attractions to its visitors, and it is expected this will be one of the largest and best meetings ever held by this association. A cordial invitation is extended to all
H. D. CUTTING, Sec.

GOODS NEAR YOUR HOME, AT A REDUCTION FROM REGULAR PRICE.

We have the following lot of goods at the places named, for which we want customers. Now, it is altogether likely that there is some one located not very far from where these goods are who will be needing just such articles, especially if he can get them a little lower than the regular price, and doesn't have to pay much freight charges on them. In hopes that there are such persons, we append a list of the articles for sale, giving the present value of the goods and the amount we will take for each lot entire. We give a number to each lot, and the name of the place where they are being held, subject to our order. Remember they are all perfect goods, just as fresh and new as if shipped from here. Remember, also, that at the price we offer them we can not break lots; each lot must go entire. In making your orders, please give the number of the lot as well as the articles contained in it, and thus help us to avoid mistakes.

No. 1. Aplington, Iowa.
Ten 2-story portico hives, complete, in flat, for comb honey, including m. c. frames, wide frames, sections, separators, thin fdn. for sec., 7 lbs. brood fdn., and enamel sheets. The lot foots up to $25.30. We will sell it complete for.................................$22.00

Wanted. To exchange for cash, three farms, five miles south of Atlanta, Ga., one with 92¼ and two with 43 acres each. Call on T. A. POOLE, near farm, or address E. B. PLUNKET,
22-23d Palmetto, Manatee Co., Fla.

FOR SALE CHEAP.

Owing to different arrangement of machinery in our new building we have for sale at half their cost the following:

Three 18-in. adjustable drop-hangers for a 2 15-16-in. shaft. Cost $10.00 each; will sell for $5.00.

Nine 18-in. adjustable drop-hangers for a 2 7-16-in. shaft. Cost $10.00 each; will sell for $5.00.

Ten 30-in. iron pulleys, 10-in. face. for a 2 7-16-in. shaft. Cost $8.00 each; will sell for $4 00.

Exhaust-fan that has run six years, but has become too small for our needs, costing over $100.00 when new; will sell for $25.00.

The hangers and pulleys are just as good as new, and a bargain to the man who needs them. The fan is some the worse for wear, but with a little repair will do good service for years to come.

THE CANADIAN BEE JOURNAL.

WEEKLY, $1.00 PER YEAR.

JONES, McPHERSON & CO., Publishers, Beeton, Ontario, Canada.

The only bee journal printed in Canada, and containing much valuable and interesting matter each week from the pens of leading Canadian and United States bee-keepers. Sample copy sent free on receipt of address. Printed on nice toned paper, and in a nice shape for binding, making in one year a volume of 832 pages 9tfb

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ad's intended for this department must not exceed 5 lines, and you must SAY you want your ad. in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. Of course, this department is intended only for bona-fide exchanges.

WANTED.—To exchange my Given fdn. mill, good as new. I will take honey, or good winter apples for it. L. BECKWITH, Berlin, Wis.

WANTED.—Honey, extracted preferred, in exchange for hives, frames, section boxes, saw-mandrels, and bee-hive machinery. What have you got, and what do you want for it?
20tfdb D. S. HALL, So. Cabot, Vt.

WANTED.—To exchange for cash, or good horses and mules, 200 colonies of bees in Simplicity frames; also 40 acres of land adjoining the city.
20tfdb ANTHONY OPP, Helena, Phillips Co., Ark.

FIRE! Fire! Fire! Brother bee-keepers, you all want my LIGHTNING FIRE-KINDLER, costing about the same, almost as necessary, and but little more trouble, than matches. Perfectly safe. No litter. Time, temper, and match saving; household convenience. It makes a fire immediately. Lasts a lifetime. Just the thing for your smokers when made one-fourth of the common size. Sent by mail for 20 cts.
20tfdb S. S. BUTLER, Los Gatos, California.

WANTED.—To exchange bees for land south of the Ohio River. Also for sale, about 120 lbs. of wax and a six-inch Pelham fdn. mill.
M. J. HARRIS, Clay City, Clay Co., Ill.

WANTED.—To exchange for extracted white clover or basswood honey, one foot-power saw; also one 10-in. Pelham foundation-mill, with dipping-tank, etc., nearly new. W. S. WRIGHT,
21tfdb 365 W. Van Buren St., Battle Creek, Mich.

WANTED.—To exchange for extracted honey, cash, or offers, one Adams horse-power, cost $40.00; never has been used over half a day. I will take $20.00 for it. It is just as good as when it came from the factory. 22-23d C. M. DIXON, Parrish, Ill.

WANTED.—To exchange 3 trios of fine Royal Imperial Pekin ducks, for sections. They are prize-winners. A few more premium Wyandotte and Plymouth Rocks to exchange for cash or sections, 4¼x4¼x2 in., as you prefer, or beeswax, or comb foundation. I have all choice birds.
22tfdb LOUIS WERNER, Edwardsville, Ill.

I STILL have 4 tested Italian queens; to close them out I will take $1.25 apiece, or the lot for $4.00; or I will take Simplicity bodies in exchange.
22d C. F. UHL, Millersburg, Ohio.

WANTED.—To exchange for pure extracted honey, apiarian supplies, or offers, one Star bicycle, but little used. Write for description.
Address C. H. WATSON, Newtown, Bucks Co., Pa.
22-23-24d

15 VARIETIES raspberries; fine plants, new varieties, in exchange for comb or extracted honey. For particulars, address E. T. FLANAGAN, Box 995, Belleville, Ill.—Eight acres in small fruits.
22-23-24d

WANTED.—To exchange for cash or offers, 2 clarionets, A and C, cocoa wood, 13 G. S. keys; used but little, and good as new; cost $40.00, will take $20.00 cash. A. LUDDEN, Shelby, Shelby Co., Iowa.
22-23-24d

WANTED.—Extracted honey for pure Pekin ducks, cockerels from Corbin P. Rocks, L. Brahmas, and Wyandottes; one black and six hybrid queens; also plants in the spring—Cuthbert raspberry, Cumberland Triumph, Mt. Vernon, and Sharpless strawberry. Please state price of honey, and what is wanted. G. A. FARRAND,

One-Horse-Power Shipman Engine

FOR SALE.

We have for sale a one-horse-power Shipman coal-oil engine that has been run 5 months. We received it in trade for a larger one, as it was too small for his work. The price of a new engine of this size is $125.00. We will sell this for $100.00, and include a 15-gallon galvanized-iron oil-tank, costing $5 00, and a galvanized-iron pan for the engine to sit in. The above engine is in first-class running order, and will be shipped from here. One of these engines, same size, has been running our county-paper printing-press for the past year, and pleases them much better than the 2-horse-power Payne engine they formerly had.

A. I. ROOT, Medina, O.

NOW READY.

Photographs of all the principal bee-keepers, including Langstroth, Newman, Root, King, Heddon, Demaree, McLain, Stanley, Given, Van Deusen, Mrs. Harrison, etc., 120 pictures, name under each, size 11x14; $1.00 by mail. Fifty of the principal ones, larger, on same size card, same price. 22d E. O. TUTTLE, BRISTOL, VT.

FOR SALE CHEAP.

Owing to different arrangement of machinery in our new building we have for sale at half their cost the following:

Three 18-in. adjustable drop-hangers for a 2 15-16-in. shaft. Cost $10.00 each; will sell for $5.00.

Nine 18-in. adjustable drop-hangers for a 2 7-16-in. shaft. Cost $10.00 each; will sell for $5.00.

Ten 30-in. iron pulleys, 10-in. face. for a 2 7-16-in. shaft. Cost $8.00 each; will sell for $4.00.

Exhaust-fan that has run six years, but has become too small for our needs, costing over $100.00 when new; will sell for $25.00.

The hangers and pulleys are just as good as new, and a bargain to the man who needs them. The fan is some the worse for wear, but with a little repair will do good service for years to come.

A. I. ROOT.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or $2.00 per annum, when given once a month, or $4.00 per year if given in *every* issue.

$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or $2.00 per year.

Those whose names appear below agree to furnish Italian queens for $1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for $1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

40-Horse-Power Engine for Sale.

Our new automatic cut-off 90 horse-power engine is now driving the machinery in all our buildings. Now, we want to dispose of our old 40 horse-power engine which has done such faithful work for us for the last eight years. It is a standard plain engine, Lord & Bowler make, 12x20, with a 9-foot balance-wheel and a 6-foot fly-wheel. We will offer it, put in good repairs, for $350 00. We will throw in the stone upon which the bed-plate is bolted, free of charge. For further particulars, write us. Whom shall we hear from first?

A. I. ROOT, Medina, Ohio.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—The demand is good for all grades, and receipts have been very large of comb and extracted, our home bee-men having kept out of the market until this month. Having glassed every one-pound section on both sides, they are reducing prices, selling 60 pounds of glass with 160 pounds of honey, making our market lower. Their crop is about 70,000 lbs. White clover in 1-lb. sections, 12@13; in 2-lb. sections, 11; in ½-lb. sections, 13@14. Dark, in 1-lb. sections, 10; in 2-lb. sections, 8@9. California, in 2-lb. sections, 9@11. Extracted, white clover, 6c; dark extracted, 4@5; California white sage, extracted, 5½; amber, extracted, 5c. *Beeswax*, 22c. CLEMONS, CLOON & CO.,
Nov. 20, 1886. Cor. 4th & Walnut St's,
Kansas City, Mo.

PHILADELPHIA.—*Honey.*—The new comb honey coming in shows good quality. There was but little comb held over, and consequently new arrivals sell well. Fancy white comb in 1-lb. sections, in paper boxes or glassed, commands 12@14c; and 2-lb. sections, glassed, 10@12c; while lower grades of both sizes go at 8@11c. Dark pungent-flavored buckwheat honey will probably be a good crop, and go lower. The crop in New York, Pennsylvania, and Vermont, is reported fair, while Illinois, Iowa, Kansas, and Wisconsin are said to have yielded well. A small quantity of Southern strained irregular honey comes here, and sells as low as 50c per gallon. The crop there is large. Eastern honey in barrels sells at 5@6c. The California crop is reported heavy, and the 5-gallon cans (two in a case) find ready sale in the East. In consequence of the big crop of this splendid California honey, and low freights, there have been a number of cars disposed of here already at 4½@5c per lb., and much larger sales are expected in cooler weather.
PANCOAST & GRIFFITHS,
242 South Front St., Philadelphia, Pa.

ST. LOUIS.—*Honey.*—We have to report the honey market dull. Market overstocked, and, to make sales, former prices have to be shaded. Choice white clover, 1-lb. sections, 12½@13c; 2-lb., mixed stock, 10@12c. Extracted, white clover, in tin cans, 5@6c. Southern, in bbls., 3@4½c, as to quality. California honey, white sage, comb, 1-lb. sections, 10@12c. Extracted, cans, 5@5½c. *Beeswax*, as it runs, 20c; selected, 22@23.
M. B. WESTCOTT & CO.,
Nov. 22, 1886. 108 and 110 Market Street.

DETROIT.—*Honey.*—Best white honey in 1-lb. sections, 11@12½c, with a large supply in commission houses. *Beeswax*, 23c. M. H. HUNT,
Nov. 21, 1886. Bell Branch, Mich.

CHICAGO.—*Honey.*—Demand light, and offerings quite free. White comb honey, small frames, well filled, 12@13c. White comb honey in same size frames, not well finished, 10@11c. Extracted ranges from 5@6c. *Beeswax*, 22@25c. R. A. BURNETT,
Nov. 23, 1886. 161 So. Water St., Chicago, Ill.

NEW YORK.—*Honey.*—There is a good demand for finer grades of comb honey, both 1 and 2 lb. sections. The market is well stocked, and with the large receipts coming in from the West we shall be obliged to reduce prices accordingly, in order to make sales. THURBER, WHYLAND & CO.,
Nov. 23, 1886. Read and Hudson Sts., New York.

BOSTON.—*Honey.*—No change in prices; demand fair. BLAKE & RIPLEY,
Nov. 22, 1886. 57 Chatham St., Boston, Mass.

CLEVELAND.—*Honey.*—The market is dull but steady. Best 1-lb. sections are taken slowly at 13@14c; second grade of white, 1-lb., 12@12½. Best 2-lbs., white, unglassed, 11@12. Buckwheat hardly salable at any price. Extracted, 6c. *Beeswax*, 25c.
Nov. 22, 1886. A. C. KENDEL,
115 Ontario St., Cleveland, O.

FOR SALE.—About 1000 lbs. of dark fall honey, for which I will take 8c per lb., delivered on board of cars. It is in 1-lb. sections, 48-lb. cases. Also 400 lbs. extra clover and basswood in same shape, at 12c.
EZRA BAER, Dixon, Lee Co., Ill.

WANTED.—A barrel of thick, well-ripened clover honey. New York or Ohio preferred. Address, with samples, W. E. SKINNER, Brightwood, D. C.

Untested Queens Ready to Mail
ALL WINTER LONG.

I have now on hand untested queens ready to send out by first mail. In regard to my responsibility, I would refer you to A. I. Root, with whom I received instruction in bee culture. The friends who order these queens during the winter time are expected to have sufficient experience to take care of them when they are received at the postoffice. In the Southern States, where the winters are so mild the bees can fly almost all winter long, of course there will be little more difficulty in receiving them in the winter months than at any other time. N. ADAMS,
Sorrento, Orange Co., Fla.

LITTLE SAMSON NO. 1.

Three-horse-power engine for sale; been used only 3 months. Made by Millar & Son, Utica, N. Y.; 24-inch balance-wheel, and 8-inch driving-pulley. Cylinder has 4-inch stroke. Governor complete. Good as new, and in perfect working order. Price $50 cash; cost us $90. F. D. WOOLVER,
23-24d Munnsville, N. Y.

ALSIKE and white clover seed at retail and wholesale. E. S. HILDEMANN,
23d Ashippun, Dodge Co., Wis.

10-INCH FOUNDATION-MILL FOR SALE.

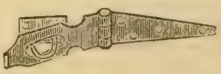
A friend at Carson City, Nevada, has one of our improved 10-inch foundation-mills, with dipping-tank and boards, that has *never been used*, he having been taken sick soon after he received it. At our present prices it is worth over $23.00. We will sell it for him at $22.00 for the outfit complete. This is a good chance for some Western bee-keeper, who wants a mill, to save quite a sum in the way of freight charges.
A. I. ROOT, Medina, Ohio.

HOW TO RAISE COMB HONEY.

Price 5c. You need this pamphlet, and my free bee and supply circular. 18tfdb
OLIVER FOSTER, Mt. Vernon, Linn Co., Iowa.

Recent Additions to the Counter Store.

THREE-CENT COUNTER.



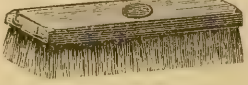
4 | HINGE HASP, entire length, 6 in...... | 28 | 2 75

FIVE-CENT COUNTER.

9 | HINGE HASP, length 10 in.................. | 40 | 3 50
Same as 3 cent one, but larger.
3 | HAIR-PINS, 100 assorted.................. | 45 | 4 00
In a neat box with 4 compartments, and 25 in each.
2 | WARDROBE HOOK, BRASS .... | 35 | 3 00
A new design; very pretty and convenient.
| SCHOOL SLATE, 10x14 frame .... | 48 | 4 50
☛We have sold slates a good while, but never so large a one as this for a nickel.

TEN-CENT COUNTER.

9 | BRUSH, RICE-ROOT .... | 90 | 8 50



This is the best thing I ever came across in the shape of a horse-brush. It is so stiff that it will take the mud off in a hurry, and yet it is not so stiff as to be injurious as a curry-comb sometimes is. The men who have used them are loud in their praise and would not be without one. I have known men to pay 75 cts. for one little if any better than those we sell for a dime. Besides being a good horse-brush, they make an excellent scrub-brush.

1 | SEWING-MACHINE NEEDLES .... | 80 | 7 00
For any sewing-machine made. Three assorted needles, cloth-stuck in a paper. These are very good needles. Three papers for 25 cents.
A. I. ROOT, Medina, O.

EXTRACTED HONEY.

HOW TO HAVE IT EQUAL TO COMB HONEY IN EVERY RESPECT EXCEPT APPEARANCE.

WITH reference to my article in last number, on page 882, in your foot-notes, Mr. Editor, you ask me to give my latest experience in obtaining perfectly ripened extracted honey, with the least amount of labor. I will do so, and "hew to the line, letting the chips fall where they may;" and if they fall on top of my new hive, and I proceed to brush them off before all your readers, I hope no one will accuse me of seeking to advertise in the reading-columns. That is something I do not wish to do; but I see that incidental advertising is an absolute necessity, many times, to the end that we may present our best thoughts; and I for one wish to present no other than my best, upon any subject that I undertake to write upon.

If you refer to my book and circular for 1886 you will notice that, wherever I mention the superiority of the new hive, as viewed by me, I usually add, "for comb honey." Now, during the past season we believe we have demonstrated that it is equally superior for the production of extracted honey, as we find it perfectly fits our theory and practice of producing rich, oily, dead-ripe extracted honey, which is in every way equal to comb only, except in appearance, and that its peculiar construction enables us to take the honey through that hive with considerable less labor than is necessitated by the use of other hives, all of which I will try to make plain further on.

Let us inquire into the philosophy of the ripening process. It is supposed by many that the capping or sealing of cells is a factor in favor of the ripening of the honey they contain. No doubt this idea has gained credence because we usually find the ripest honey within capped cells; but such is not the case, however; for the ripening process goes on more slowly after capping than before; and it would not continue at all after capping but for the fact that the material of which these caps are made is more or less porous. Just how or why, I do not understand; but I believe I have demonstrated that the peculiar heat and currents of heat contained within the hive of a populous colony possesses, in an eminent degree, a peculiar superiority for perfecting the ripening process; besides this, before the honey is sealed, and after the time that many extract it, if left in the hive we are told that the younger bees several times re-swallow and re-eject it into the cells—another thing which gives it a rich oily nature. Be this true or false, after the most thorough experiments with the artificial ripening process mentioned in last issue, I have found that, some way or other, there is no other extracted honey equal to the hive ripened article. Believing it is clear to the reader that, while cappings and ripe honey are usually found together (because the bees will not cap it until it *is* ripened to a certain consistency, at least but that capping), rather than being a cause, is a hindrance to such ripening, I have no doubt but that my readers of a larger experience will readily conceive the idea that a judicious and thorough system of *tiering* will have a great tendency to prevent capping, and, at the same time, aid the ripening process.

We use from two to four extracting-supers, each having the full capacity of the 8-frame Langstroth hive; and as soon as the bees began to seal the combs in their first super, we lift it, sliding an empty one under it; and if they still persist in capping the combs of the upper one, we again slip under both another one, all the time keeping those furthest advanced high up, where the ripening process is going on, but where the bees are discouraged from immediately capping the cells.

This tiering system is not new, but I am dilating more especially with regard to a radical use of it for the special purposes above mentioned. Before we consider the honey in any super to be "dead ripe," we usually find a minor portion of the cells of nearly every comb capped over; but did you never notice the fact that it is four times as much work to uncap a comb which is completely sealed as it is one only half capped over? This is because the first cells capped are those most elongated, which are very easy to uncap, while it is the lower surfaces that make us all the hard work. You no doubt remember that we use the new hive for extracted honey by adding brood-cases in the place of surplus-cases. We use one and two brood-cases for a brood-chamber, according to the time of year and system of "contraction"—a most valuable system for the production of comb and extracted honey, and one which, if I remember correctly, has not been fully described in GLEANINGS. Whether our brood-chamber consists of one or two brood-cases between it and the extracting-department, composed of a suitable number of other brood-cases, we use the combined wood and metal queen-excluding honey-board, described and illustrated on page 613, Aug. 1, 1886.

Now, with these shallow sets of frames securely held within the cases, we practice the tiering method to its greatest perfection because of their shallowness, and by virtue of the shaking-out function gained by the peculiar construction of the cases (a function which I consider the most valuable of any contained in my hive or any other) we are able to remove these cases from the hives with the certainty that there are no queens or brood within them, shaking out nearly all the bees with a few motions, placing the cases in our screen-house till the few remaining have deserted, all of which we can do without exposure to robbers, even when they are most persistent, and carry the cases to our honey-table, loosen the screws, lifting the case away from the frames, all of which set up ready for the uncapping-knife. I find these shallow combs very much easier to uncap than deeper ones. I found this out 15 years ago, when using shallow combs in Langstroth frames. These frames hang in the extractor in pairs, side by side, hanging on the projection of the end-bars, which, you remember, are wider than the top and end bars; and when used in common machines that are not automatic. In reversing the combs they can be turned around without lifting out of the machine, as is necessitated with L. frames. It will be seen that it is not only true that these shallow brood-cases are best for the tiering method, where perfect ripening of the honey is desired, but it is also true that we can take a surplus crop through them with less labor than with any other frames, which, I believe, exactly answers the question you ask on page 883.

It may be claimed, contrary to the above, that there is quite an expense attached to the supply of so many sets of combs and supers; to which I reply, "I grant it;" but that does not disprove that their use will give us a No. 1 extracted honey, such as will sell itself, and that, too, without practicing the compressing method, which costs us nearly half of our honey-crop. If we should figure an interest upon the investment I now have in thousands of nice combs from full sheets of fdn., on wires, it might prove that my 1886 crop has cost me 1 cent per lb. more because of this outlay; but if you will allow the bee-keepers who have purchased most of my crop—purchasers who are the best of judges of quality—to speak through GLEANINGS it will give your readers a fine opportunity to judge as to whether or not such perfectly ripened honey is worth 2 to 3 cents per lb. extra. JAMES HEDDON.

Dowagiac, Mich.

Friend H., there are several good points you make in the above. The plan of leaving the whole crop of honey on the hive, over the bees, until the season is over, belongs to friend Dadant, I believe, although before he gave it in his little book we did the same thing one season, when we were greatly pressed for time; namely, we piled Simplicity hives one over the other, until they were, some of them, four or five high, and the result was just about as you state it. When the combs were raised up before they were well capped over, the bees seemed to leave them partially uncapped, and the honey obtained from these piles of hives was certainly equal to any we have ever secured. I think you are right, too, in saying that these small frames, or shallow frames, rather, are much easier to uncap than full-sized L. frames; and your third point, of being able to reverse them in any common extractor, it seems to me, is quite a big item. The assistant who does the uncapping, uncaps both sides, and stands the little frames on a shelf, board, or, perhaps, still better, a couple of strips with a pan underneath to catch the dripping. The broad ends with only a narrow frame will keep them upright of themselves, which will be quite an advantage; then the one who operates the extractor, instead of taking the heavy comb with both hands will take two smaller ones, one in each hand. When uncapped he reverses the two, one in each hand, as quick as he would reverse a large one, granting there were room inside of the extractor to do it. In working the shallow frames for extractors, if I understand you, you simply raise each tier of combs when nearly ready to cap, and put an empty case of similar frames under it, and so on until the bees gather all they are going to for the season, leaving every comb on the hive until the season is over. I am inclined to think that bees will store more honey where none is taken away from them than where we keep "robbing" them all the while, as our Southern friends put it. Of course, we can not work this way for section honey, for it would be soiled and spoiled for market; whereas, for extracted honey it is just what we want. And this reminds me that a real nice well-ripened article of extracted honey is often really *nicer* than a great deal of our very clean white perfectly capped comb honey. It looks, to me, just now as if quite a number of us might think best to try shallow combs for extracted honey another season.

HONEY, AND ITS PRESENT LOW PRICES.

SOMETHING IN REGARD TO THE MATTER, FROM ONE OF THE LARGEST, IF NOT THE LARGEST, HONEY-DEALER IN THE WORLD.

I MAY remark to our readers, that I wrote to friend Muth in regard to the letter from friend Park, on page 812, Oct. 15, 1886. The following is his reply:

Friend Root:—I am acquainted with the quality raised in the neighborhood of our friend Park. It is a nice article, rather above the medium quality of Southern honey; but we have no use for it now, because the demand is very slow from manufacturers, to whom only we can sell Southern honey, and because we have still on hand nearly 300 bbls., which we bought and paid for some 12 or 18 months ago. Besides the above, we have 55 bbls. more, sent us contrary to our advice, for which we have not paid. But they were sent us by our friends in good faith, that we would sell them before this, and none of us could apprehend that the demand from manufacturers would let off so. We now make to each one an offer for this lot. A few hundred barrels of honey has never troubled us much, as we turned out 10 to 30 bbls. a week, one or two years ago. We supplied a number of bakers, the best of whom got 5 bbls. a week steadily for 2 years or more. We supplied, also, regularly, a number of tobacconists, the best of whom received 3 bbls. every other day. We have not lost any of our customers, but they don't need as much as they used to. Our best baker orders now 5 bbls. in two months, and our best tobacconist one or two in a month. The one says: "Honey-cakes are played out;" and the other, "There is no money in tobacco now, and factories run only to a certain extent." Similarily say the rest.

I should be sorry for our Southern friends if the demand for their product should not revive; and I believe that the present dullness, prevailing in almost every branch of business, is the only cause for the stagnation in the trade in dark honey.

Our jobbing trade for clover honey in our square glass jars and tin buckets is very good this fall, and we have sold very many lots of nice comb honey. We have no reason to complain of this branch of our business. However, honey is too cheap to satisfy producer or dealer, and low prices are generally no stimulus to business.

We have used extensive efforts to introduce extracted honey, and to stimulate demand, and we thought that we had succeeded until lately.

If we don't supply all, we supply certainly 9 out of 10 bakers in our city with honey. They all use more or less, but—while we are thankful for all small favors, we want more, and we are used to larger sales. CHAS. F. MUTH & SON.

Cincinnati, O., Nov. 18, 1886.

The above is somewhat discouraging, I grant; but it is best for us to know the real facts, even if they are discouraging, and then we shall be prepared to face them. This honey that sells so very low is not, as friend M. has already decided, of the very best quality. I have, in our back numbers, mentioned the honey from alsike clover, obtained by friend Goodrich, who exhibited the crop at the Ohio State Fair. Now, although we have tons of honey on hand (and some of it we offer as low as 6½ cts. per lb., by the quantity), we have just offered friend Goodrich a price that amounts to something like 12½ cts. per lb. for what alsike clover he has left. It is what we call "gilt edge," and we expect to get a "gilt-edge" price for it. The honey from the South does not seem to bring as good a price as the white clover of the Western Reserve; and the moral seems to be, that our Southern friends will have to encourage the growth of the clovers—red, white, and alsike. The latter, I believe, is ahead of all where it thrives naturally.

TEASEL CULTURE.

CAN IT BE PROFITABLY ENGAGED IN BY BEE-KEEPERS?

THE seed is sown, usually, as soon as the ground can be thoroughly worked in the spring, as it requires plenty of moisture, and more time to germinate than most seeds. The sowing was formerly done by hand-drills in marks previously made, three feet apart; but now the ordinary horse-power grain-drill is used to some extent. If sown with a hand-drill, the seed is covered with either a rake or brush, or sometimes an ordinary field-roller. The plant seldom comes up in less than two weeks, and is not unfrequently four weeks in making its appearance. At first, none but an experienced eye can tell it from a Canada thistle that has just come up from seed. But the first set of two or three true *leaves* places the plant beyond any danger of getting cultivated up as a weed.

The first hoeing begins soon after corn-planting, and is accomplished by passing, with a light small hoe, up one side of the row and back on the other, cutting as close to the plants as possible, and always pulling the dirt from the plants. The horse-cultivator is used freely, and it is wonderful how close an expert will work to the row without injury. The first hoeing is generally accomplished before any of the plants are more than an inch high.

The second hoeing should not be delayed more than two weeks after the first. At this time *every* weed is taken out; either with the hoe or fingers, and the plants thinned to from 4 to 8 inches in the row.

This is accomplished from July 1st to 10th, and well cultivated with a horse twice or three times between each row. They are then allowed to go untouched until the following spring.

Of late years, growers have been in the habit of planting half a crop of corn, plucking the ears off, and leaving the stalks to catch the snow (they are liable to winter-kill if uncovered in severe cold spells). I have, with good results, omitted the corn, and with a plow turned a furrow right on to the plants late in the fall.

The first season, the plant flats out; the leaves, lying on or near the soil, make a solid green belt nearly two feet wide, and not more than six inches high. Walking or driving over a field does apparently no injury. If they survive the winter, as soon as the ground can be worked they are thoroughly cultivated (but seldom hoed), and the corn-stalks gathered off. Cultivation should be kept up until they begin to "run," which is early in June At this time a stalk shoots up very rapidly from the center of the plant. It is so brittle that a slight push will snap it off. This stalk reaches a height of 4 or 5 feet, and terminates in what is called the "king teasel," or the largest head on the plant (2½ to 4½ inches long). Below the "king," several branches will start out, each bearing teasels, or heads. The center head of these branches, or laterals, is called a "medium." "Mediums" are from 1½ to 2¾ inches in length. From these laterals spring still other branches that bear still smaller heads called "buttons." These are 1 to 1½ inches in length. One plant will produce from 10 to 25 heads.

They begin to blossom early in July. The "king" blossoms first; the "medium" next; and the "buttons" last. Each individual head remains in blossom from seven to ten days. The whole season I should put at about 25 days. Of course, the largest number of heads would be in bloom about the middle of the 25 days.

As soon as the blossoms all fall off, the heads are cut (one at a time) with stems from 4 to 6 inches long, loaded in wagons, and drawn to the dryhouse, where they are spread on scaffolds and allowed to remain until they are dry. They are then ready for the middlemen, who buy them by weight (6 cts. per lb. is the present price). With shears they cut off the long spikes at the base of the teasel, as shown in Oct. 1st GLEANINGS, p. 769 (a very good cut). The stems are cut to a uniform length of 4 inches, and assorted into sizes according to length. A pound of "kings" is worth as much as three pounds of "buttons." They are packed by hand, one at a time, in large boxes, ready to ship to woolen-factories, where they are used in raising a nap on cloth.

The teasel district is not more than ten miles square. The soil and climate must be favorable, to grow them of good quality. They have been experimented with in other parts of the State, and in other States are said to have produced vigorous plants; but the teasels at maturity lacked firmness of hook, and at present I know of no place where they are grown, except here and in Europe.

C. M. GOODSPEED.

Thorn Hill, Onondaga Co., N. Y.

And so it would seem, friend G., that there is not much hope for bee-keepers to raise teasel, unless they raise it for honey alone, which very likely won't pay; but as there are woolen-mills all over our country, it may be worth while to test the matter and see if it is not likely that *good* teasels can be raised in other places as well as in this favored ten miles square. I would advise bee-keepers to talk with the proprietors of woolen-factories, and see if some arrangement can not be made to at least test the matter. We certainly do not want to import teasels from foreign countries, unless it has been well proven that just as good ones can not be raised here at home.

SHOOTING TO BRING DOWN SWARMS.

INVERTING TO PREVENT SWARMING.

A FEW weeks ago you asked for reports about shooting into swarms to make them settle, and about inverting hives to prevent swarming. Three or four years ago a swarm came out when I was in the field. My wife first shot past the swarm. This did not seem to affect them. She then shot right into them; and, although they had by this time started to leave in earnest, they came down as quick as possible, and were hived all right.

Last summer I had a prime swarm cast a swarm, but the swarm did not settle, but went back to the hive again. I inverted the hive (a Shuck hive with a queen-excluding honey-board), and they gave no more trouble.

I don't like queen-excluding honey-boards made of wood. The bees fill the spaces too much. I should be glad to hear more from those who have used the combined wood and zinc boards.

A FOLLOWER FOR THE HEDDON CRATE.

For getting sections out of cases made on the Heddon principle, I use a follower made as follows: I dress a piece of 2×4 scantling to the proper width; a piece the same size, but ⅞ inch thick, is nailed on top with a narrow piece ⅞ inch thick, separating them at each end. In the top-piece I make a hand-hole 1 inch by 4. I support the cases on a bench, as recommended by Mr. Heddon.

BEE-BRUSHES.

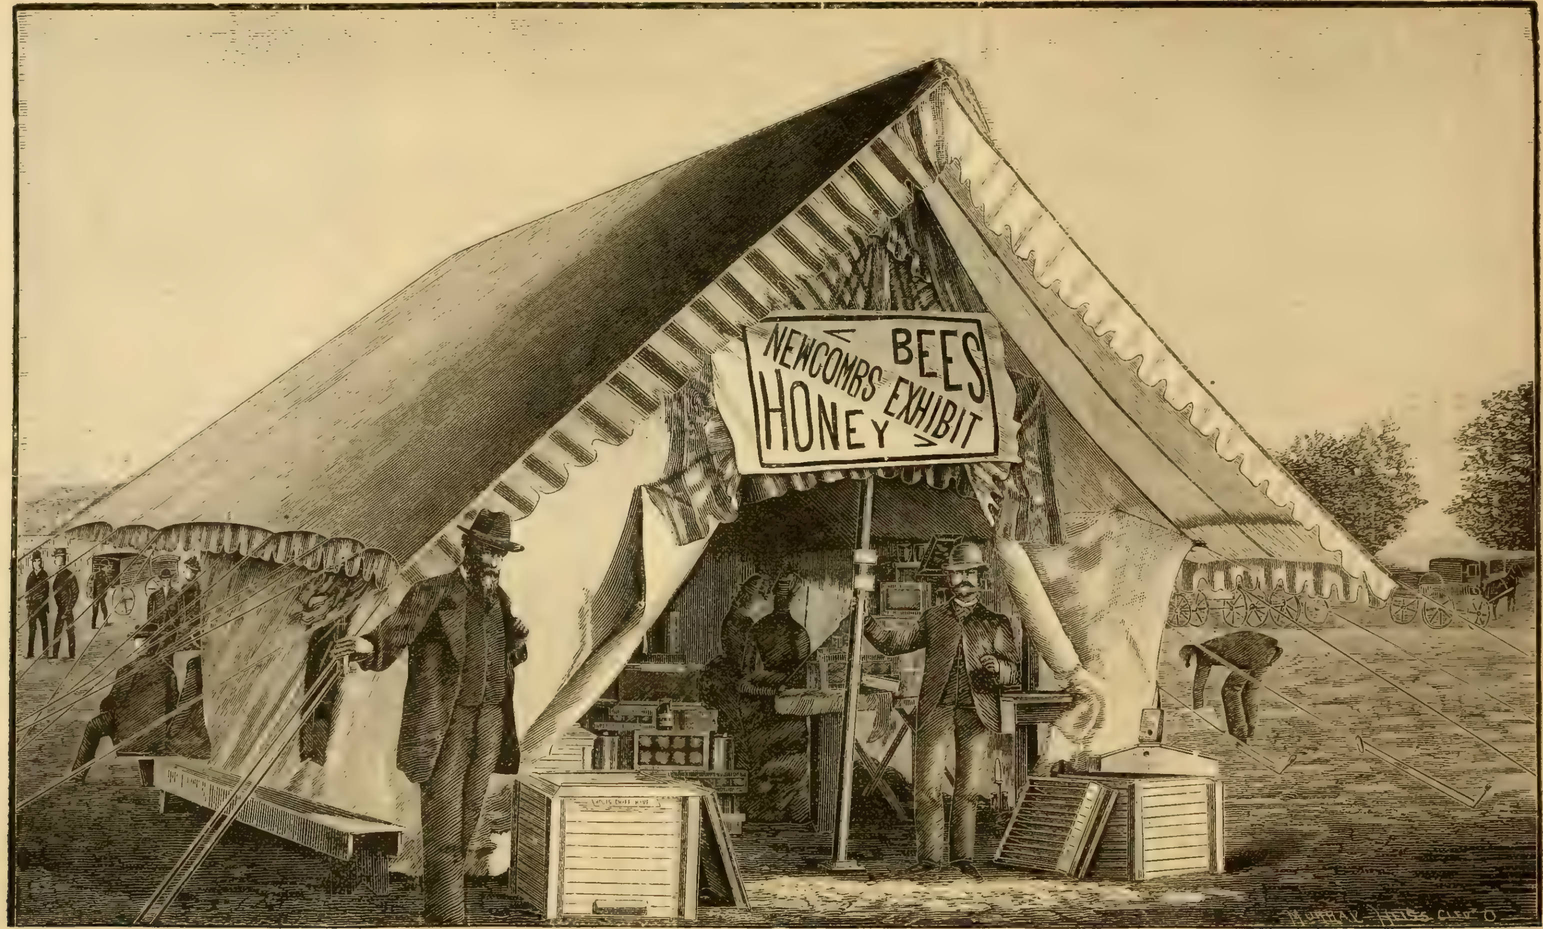
Some one recommends fastening the bee-brush to the operator with a string. I have tried it this season; but when the cord is sufficiently long for convenient use, the brush is sometimes in the way. I think a light rubber cord would be an improvement. If the cord passed through a loop or button-hole at the waist, and were fastened to the collar-button, it would hold the brush close to the body when not in use. 6—G. M. THOMSON, 25—51.

Grand Junction, Iowa, Nov. 20, 1886.

FAIRGROUND EXHIBITS.

A GLIMPSE OF A YORK-STATE FAIRGROUND HONEY-EXHIBIT.

IT is unquestionably one of the great helps toward educating the people up to the capabilities of modern bee culture, to take advantage of our State and county fairs; and it well behooves us to bestow thought and money in devising ways and means to make these exhibits attractive to those who attend our fairs. The engraving opposite gives us a glimpse of one of the best of these arrangements, in my opinion. I do not know whether the managers furnished this attractive tent for the honey-exhibits or not; in any case, I think you will agree with me that the whole arrangement is quite taking to the eye. Inside there is plenty of room, and things are so nicely arranged that even the ladies find it an attractive place. A couple of windows are shown in the cut, to make it light and airy, enabling the occupants to look out over the grounds. Around the outside are benches, affording a seat, while the weary visitor finds a shady place under the wide canopy of the projecting veranda around the tent. The doorway is tastefully looped up to make it look inviting to visitors, and a pretty card attached to the center-pole tells everybody what the tent is for. "Root's chaff hives" stand prominently in the foreground. Honey in jars, cans, and sections, stands a little back of it. On the other side is a Bingham smoker, as we take it, a case of the new shallow frames



NEWCOMBS BEES EXHIBIT
HONEY
MURRAY HEISS CLEV O

E. R. NEWCOMB'S HONEY-EXHIBIT ON THE FAIRGROUNDS. POUGHKEEPSIE, N. Y.

tipped up against the hives, and inside we shall doubtless find pyramids of honey, beeswax, and the various utensils for working with the honey-bees. How very natural our friend in the foreground looks, with his thumb in the arm-hole of his vest! One can almost catch a sly twinkle in his eye, and no doubt he could give us "piles" of information while he made us feel happy by his occasional jokes and pleasantry. I tell you, my friends, a successful bee-man, fully up to the times, is a nice man to talk with. Yes, so is a successful bee-*woman* a nice woman to talk with; and I should not wonder a bit if our honey-shows on our fairgrounds have a good deal to do with making people want to go to the fair next year.

The above exhibit was made by Mr. E. R. Newcomb, Pleasant Valley, N. Y.

THE MARKINGS OF QUEENS AND THEIR PROGENY.

CYPRIANS, SYRIANS, ETC.

EDITOR GLEANINGS:—Nearly every customer who orders a queen wants it to be a fine "yellow one;" and if it should not prove to be just as yellow as they pictured it they are a little disappointed when it arrives. All our queen-breeders know that this is usually so in almost all instances. Many bee-keepers suppose that, if a queen is of a bright beautiful yellow color all over her abdomen, she will, as a rule, produce finely marked bees, if she be purely mated. This is not so. The finest-colored queen ever bred, if mated to a dark-colored drone—or rather a drone reared by a queen that produces a poor-colored progeny—will invariably produce a poor progeny herself, while, if mated to a fine drone, equal in all respects to the color of the queen to be mated, then their progeny will be an exceptionally good one.

Some of the finest-marked progeny of worker-bees from queens I ever had, came of some of my dark-colored queens—these, too, that had rings on the rear edge of the last three or four segments of their bdomens. In other instances I have had some of the poorest-marked bees I ever had, from some of my very yellowest-colored queens, those which had no dark rings, and only just a speck of black on the tip of their abdomen. Real dark queens will produce mostly a dark progeny of queens, when used to rear queens from; still they will occasionally produce a queen that is as bright as the brightest are. The reverse is the case with real yellow queens. They will, as a rule, duplicate themselves in their queen progeny, yet will occasionally produce real dark-colored young queens, those having rings (black) on the last segments of their abdomens. Judge Andrews, of McKinney, Texas, makes the claim that all queens which show black rings on the hindmost part of the last three or four segments of their abdomen have in them black blood; that these rings of black on the segments are evidence of black blood in such queens as show them; also that *pure* queens should duplicate themselves in their queen progeny. If we are to accept these claims as correct, for the purity of any race of bees now in America, we must certainly discard our Italians, Syrians (Mt. Lebanon strain), Carniolans, Cyprians, and their crosses.

I have never yet found that queen—although I have been on the alert to do so for the past four years—which would invariably duplicate herself in her *queen-progeny*. I have had many that would do it in one batch of 12 or 15 cells, when from the very next batch of 12 or 15 cells reared from eggs of the same queen, there would hatch two or three dark-winged queens.

I *think* G. M. Doolittle made the statement in the present volume of GLEANINGS, in his communication on "Queens and their Markings," that Syrians and Cyprians, as a rule, produce brighter-colored queen-progeny than any other race. This is just contrary to my experience. I find that, as a rule, the best-domesticated Italian queens produce the yellowest queen-progeny of any race we have. I think our best-domesticated bees of any race are superior to any newly imported ones. Syrian queens, bred of a select first-grade queen from Mr. Frank Benton, direct, all showed dark rings on the segments of their abdomen, even the very brightest ones; and many of them were quite bright too.

Cyprians bred in 1885 from a queen I got of B. F. Carroll, Dresden, Texas, were similar to Italians in the markings of the queens, some quite bright, and others quite dark. I have always doubted the purity of the Carroll queen as being genuine Cyprians, and now I do more so than before, since I got a first-grade Cyprian from Mr. F. Benton, mailed at Larnaca, Cyprus, July 19, 1886, and received August 18, just 30 days making the voyage, and not a dead bee in the cage. There is much difference in the temper and qualities of the imported Cyprian, compared with the Carroll stock, the imported being much more docile; and then they are a smaller bee, with a more point-shaped abdomen than the Carroll stock. The queens reared from this imported Cyprian are all much darker than Italian queens are; but the worker-progeny are extremely well and very uniformly marked, and all the bees look just alike, young and old (matured bees), with the exception that many of them show plainly four distinct yellow bands on their abdomens.

I have two queens reared of this Cyprian, and mated with my American-albino-Italian drones, and their progeny are certainly the finest-marked bees for a first cross that I ever saw, and appear to be excellent workers, so far as tried.

Dr. Geo. L. Tinker and myself exchanged a queen this season. I gave him a select American-albino-Italian queen in exchange for a select Syrio-Italian queen, and I frankly admit that the doctor's Syrio-Italians come the nearest to rivaling my American-albino-Italians of any bees I ever have had of any breeder. The doctor deserves the praise and patronage of our bee-keepers, beyond doubt, for such grade of bees. 4—ABBOTT L. SWINSON, 71—70.

Goldsboro, N. C., Nov. 22, 1886.

Friend S., if I am correct, B. F. Carroll does not claim his Cyprian queen is full blood. He does claim, however, I think, that his strain has given wonderful yields of honey.—After we found out the temper of the Cyprians, few if any of us wanted full-blooded stock, as it is well-known they are very much milder in temper after being crossed with the Italians. There is also quite a difference in all imported queens, if I am correct. Are you not breeding more for looks than you are for honey-gathering qualities? We want the honey—that is the great point.

DR. C. C. MILLER, OF MARENGO, ILL.

SOME REMINISCENCES FROM MEMORY, OF FRIEND MILLER.

I AM glad to be able to give the readers of GLEANINGS so good a picture of a contributor who is now so well and so widely known by his articles, and by his contributions to other journals as well as to GLEANINGS. Those who have met him at our large conventions will, I think, agree with me that the picture is a good one.

I may have told you something before of my first acquaintance with Dr. Miller; but if I did, it won't do any harm to tell it again here. It must be something like fifteen or sixteen years ago that a stranger called and wanted to talk about bees. I was just then getting ready to go out bee-hunting, in order to be able to write intelligently on that subject. So many had come to see me about bees that I felt a little impatient at being hindered just then; but as this visitor seemed to be quite an intelligent man, I told him I should like to have him go with us, if he cared to, but I didn't much expect he would relish a tramp in the woods. He was not so stout a man then as he is now, but he looked to me then more like a dry-goods clerk, or a young doctor or lawyer, than he did like a farmer or even a bee-keeper. I was a little surprised when he said he would like to go, above all things.

While we were in the woods, looking up among the trees for a bee-tree, I began whistling, absently, a simple little air from Root's Curriculum, for I was then taking music-lessons. He made the remark, that what I was whistling was rather pretty. I told him I thought it very pretty indeed, even though it was just a simple little exercise for beginners in music.

"Well, I am glad you like it, Mr. Root, for it is something I composed myself."

I turned about and stared at him, and concluded that he was not only a brag, but that he was untruthful; and I replied, a little dryly, that he must be mistaken. It was an exercise I had just learned from the Curriculum.

"Can't help it, Mr. Root; I composed it, all the same."

As he saw I didn't believe it he said nothing more about it; but when we got home he asked if he might look at our Curriculum; and as he did so he placed his fingers on a foot-note on one of the pages, to the effect that Dr. C. C. Miller had assisted in the compilation of the work. I nodded.

"Well," said he, "that refers to me. I am Dr. C. C. Miller."

Of course, we asked him to play for us; and by and by we were very glad to have him consent to stay over night with us, and, in fact, make our home his home so long as he remained. We went over the bees and other things; and finally, just before he was about to take his leave, he surprised me still more by a little talk something like this:

"Mr. Root, I think I may confess now, that I had a plan and purpose in making you this visit, besides learning what I could

DR. C. C. MILLER.

about bee culture. I have read your writings a good while, and I knew you, even if you did not know me. I wanted to say something to you; but I felt that, before I could say it, I must have you get acquainted with me, and I wanted to win your confidence, that my words might have influence with you. I have now got acquainted, and I think I have won the friendship and confidence both of yourself and your good wife, if you will excuse me for being somewhat presuming."

He paused here, and I believe that my wife and I both felt a little as did the good people over in England when Moody and Sankey first came among them. The people were anxious to know what the evangelists had to sell, or whether they were agents for a new musical instrument, or something of that kind. Dr. Miller, however, soon dispelled these thoughts by something like this:

"Mr. Root, I want you to be a Christian. I want you to exert the inflence you possess, and to use the hold God has given you on the hearts of the people, for the cause of the Savior."

I can not remember what else he said just then, but I hastened to tell him that I was already in favor of Christianity and good morals, and I expected him to "let up," as the expression is, in the same way I had induced our pastors and other good friends to pass me by. He had no intention, however, of giving up thus easily. He told me that he who is not *for* the Savior is against him, and kindly and pleasantly insisted that my influence was on the wrong side. I quizzed him and questioned him, and tried to make him compromise a little, but he held fast to the Bible and to Bible texts with such earnestness and faithfulness that I never got over it. He talked with all the energy I had heard drummers and runners talk to sell goods, but he had nothing to sell. He held up before me Christ and him crucified, and pointed me to the open door of salvation — open to all who will accept it without *money* and without *price*.

When I began to get intimately acquainted with Prof. Cook, the two men reminded me so forcibly of each other that I wrote to both that they must get acquainted with each other. In a little time they became acquainted, and I was not disappointed. Once when in sore trouble as to where duty lay, it occurred to me I should like the counsel of two such men as Dr. Miller and Prof. Cook, more than the counsel of any other two men I knew of in the world. As it was during a State convention, I started out, although it was somewhat late in the evening, to find them. To my surprise I found them rooming together; in fact, they were just getting ready to retire. I stated the case to them; and after one proposed that we should take the matter to God in prayer, we knelt down then and there, and had a little prayer-meeting. I shall always remember the prayers of those two friends; and I shall always remember, too, the feeling of safety and security I felt as the little meeting closed. It does not seem to me that one can go very far wrong when he takes the advice, given after praying over the matter, of two good Christian men. I do not mean that the two think *alike* on all the great issues before us, for indeed they don't; but they are both earnest, faithful servants of the Master, and devoted heart and soul to the good of our people and to the good of our country. It does me good to see them both brighten up at the thought of any public movement for the well-being and happiness of humanity, especially for the youth of our separate States.

Dr. Miller injured his health by incessant hard study; and after practicing medicine to some extent, and giving it up on account of his health, he made music a profession. This he also abandoned for the same reason, and shortly after I first saw him he took up bees, with the prospect of small pay, when he was offered a salary by some of the leading music-publishing houses of our country, that might dazzle almost any one of us. He felt that the blessing of health, with God's sunshine and outdoor air, with even a small income, is better than large salaries and a broken-down constitution.

ARTHUR'S BEES.

A Story for Boys.

BY MRS. CASTELLA WHITMAN.

Continued from Nov. 15.

WATCHING his bees through the remainder of the season was a pleasant pastime for Arthur. He had always been a faithful boy, but it really seemed as if a new motive prompted him to greater exertions. No surplus honey rewarded him, but by being carefully protected through the winter they greeted him the following spring, when all nature was springing into new life; but, alas! how little did this family know what great sorrow was to come upon them! The darling baby-sister, the pet of the household, scarce two years old, was snatched from their midst, and laid to rest in her flowery bed on Decoration day. This great grief so unnerved the mother that it was a long time before she seemed herself again. Though always tender and self-sacrificing, she appeared doubly so now, and nothing was left undone that she could do to develop any thing noble and manly in her boys. Still, she was as ready to correct them, if she considered them in fault, as to commend when they had done any thing worthy of it.

Arthur's bees remained in their old hive, instead of being transferred, as he anticipated. They swarmed twice. The second swarm came out on the Fourth of July, and the children said they were holding their anniversary.

Thus two new hives were placed near the stately old barrel hive, forming quite a contrast, as Arthur's father had exercised a great deal of skill in making them.

I will hastily pass the remainder of this season by. Arthur, too, was anxious to see what another year had in store for him, notwithstanding he was often admonished that the present only is ours—the future is uncertain.

Before he scarcely realized it, another winter had passed, and it was time to place his bees on their summer stands. It was indeed a pleasure to the older members of the family to see the interest Arthur still maintained in them. Scarcely a day passed but that he would spend a few moments with them as he went to or came from his work; and occasionally have I had a glimpse of him at sunrise, partially sitting by the side of a hive, watching the busy workers.

As the season advanced, the work on the farm increased, and it was with a great effort that Arthur and his father kept their work up and made hives for the bees. Two of the colonies (as they had by this time learned to call them) swarmed three times apiece, and the third one twice, thus requiring eight new hives.

By this time the father expressed as much enthusiasm as Arthur himself. The family had noticed of late, that, in speaking of the bees, Arthur would call them *our* bees. I will here remark, that, though he possessed an impulsive disposition, he also possessed a manly spirit, which would not permit him to accept of any title or honor that did not rightfully belong to him; thus the term "our folks' bees" was universally accepted afterward. One day, as Arthur's father was glancing over his *Agriculturist*, he came across the following advertisement:

FRIENDS, if you are in any way interested in **BEES** or **HONEY** we will with pleasure send a sample copy of the **SEMI-MONTHLY GLEANINGS IN BEE CULTURE,** with a descriptive price-list of latest improvements in HIVES, HONEY-EXTRACTORS, COMB FOUNDATION, SECTION HONEY-BOXES, all books and journals, and every thing pertaining to Bee Culture. *Nothing Patented.* Simply send your address *plainly written* to **A. I. ROOT, Medina, O.**

"Nothing patented!" he ejaculated; then after giving the subject a little thought, he sent his address as recommended.

I have often heard Arthur's mother speak of the day the circulars, as she then called them, arrived. She was expecting company, too, that she felt unusually particular about. I do not suppose that every boy knows, but many a boy's mother does, how many extra steps are to be taken, and how much anxiety such an occasion requires, especially if they live on a farm where such a variety of work must be attended to.

Arthur and his father, notwithstanding they seemed so intent on perusing their circulars, assisted her somewhat, and the day with its cares and enjoyments passed away. During the remainder of this busy week the mother came across their papers many times, but only to put them in their proper place.

The next Sabbath morning dawned bright and beautiful. Arthur remained at home with his mother and younger brothers, while his father and the remainder of the family attended church.

Arthur spent the greater part of the day in reading, as usual. His mother had but little time to read, even Sunday, until dinner was over. It being ready at the usual hour for that day, she sat down with her paper in hand, waiting for their return from church. It was with a great deal of anxiety she watched the time go by, as they were obliged to cross a certain bridge that had been condemned. Arthur, noticing her concern, said, "Mother, perhaps you will find something interesting in this, handing her one of the said circulars, which proved to be GLEANINGS IN BEE CULTURE.

She was quite surprised, on glancing over its contents, to find it of so different a character from what she expected. It truly was *Gleanings*—articles written by different persons here and there all over the country, and then notes or comments by the editor on nearly every one. And still further on came "Our Homes," so full of such good thoughts and suggestions that they all thought the time was very pleasantly as well as profitably spent. Arthur's grandparents came in about the time his mother sat down to read, and they too were attentive listeners.

Thus the days and weeks of the summer flew by, Arthur often reviewing this number of GLEANINGS that I have referred to, and the price list that accompanied it. He often wished that they could subscribe for it. It seemed impossible just then, as his own weekly paper could not be dispensed with, and he had tried very hard to pay for it himself for the last few years. The price list not only gave the prices of bees, queens, hives, and all that pertained thereto, but also prices of their counter store connected with the factory. It was really surprising to note the many useful articles it contained.

The autumn months were near at hand, and so was Arthur's birthday. His mother could not think of letting it pass by unnoticed, as it was the family custom to present at least some little token of remembrance. Thinking it would be a pleasant surprise to receive something from Mr. R.'s store, she wrote an order for the same and also inclosed the price of GLEANINGS for Arthur's father, he having already sent for the A B C book. Perhaps it is needless to say, that, as such days returned, they all enjoyed it as much as the one who received the gifts. Nothing worthy of note transpired during the remainder of this year. The family spent many happy evenings during the winter months listening to Arthur as he read from his journals. They wisely reported the discouragements as well as the encouragements in bee culture. Thus by spring Arthur had gained much valuable information. Nor was it long before some of it was put in practice. Scarcely had his winter school closed when their bees were again on the wing. A little plot of ground was neatly arranged, and the eleven hives were set out in order upon it, quite after the manner of our modern apiaries.

By this time it was plainly to be seen, that, if they continued to keep their bees, something further must be done than simply to make a hive as it was needed. Thus far they had never been to any expense as far as dollars and cents were concerned, neither had they received any returns from the bees, save some honey for family use. Arthur and his father concluded it best to send for two hives of different styles before making any further arrangements. Being sent by express, they were soon at hand. Arthur's father brought them home in the evening, and the delighted children could not think of going to bed without seeing them set up, as they came in the flat.

It was evident, from the expressions of the whole family, that they more than met their expectations. They indeed looked like miniature houses, with their little porticos in front.

There was no more time to be lost. The season when they would need their hives most was rapidly advancing; but the contrast between the old and these new hives was so great, not only in appearance but in point of excellence, that, possessing the spirit of the times as much as the father and son both did, they could not think of using the old box hive any longer, even if money was scarce, and there were many other needs also; so a second order was soon made out.

They naturally expected there would be some delay, as they had taken time to get their sample hives, and well knew that other orders in advance would receive attention first; but as days lengthened into weeks, and yet they received no notice that they had been shipped, they grew quite impatient. Their bees had already commenced swarming, and had to be hived as before.

To be continued.

A GOOD REPORT FROM WEST VIRGINIA.

SOME VALUABLE SUGGESTIONS ON PRODUCING AND SELLING HONEY, BY ONE WHO MAKES BEES PAY.

I AM located in the "Pan Handle" of this State —that narrow strip of land lying on the Ohio River between the States of Ohio and Pennsylvania. The average yield in this part of the State might be put at 40 lbs. of comb honey, spring count. After some sales last spring I had 56 colonies left in my home apiary, and 14 colonies three miles out. The 56 swarms were so closely evened up by interchanging brood that they all had cast swarms within five days from the issue of the first swarm. Twenty-four first swarms in one day! When swarming had ceased there were but 56 colonies in the apiary, as before.

SWARMING, AND HOW TO MANAGE.

At the beginning of the surplus yield, each hive was supplied with a case of sections—room for 2000 lbs. of comb honey for the 56 colonies. By the time the sections were two-thirds full, swarming began. My queens are all clipped; and as fast as swarms issue they are hived and placed near the old stand.

All swarming for the day having ceased, the cases of sections are taken off; the combs in the hives are extracted of all the honey; queen-cells are destroyed, drones' heads shaved off. They then are returned to the original hive, where they are soon cleaned up by bees remaining at the old stand. The cases of sections are put in place; and just at sundown, each hive having that day cast a swarm, it is re enforced by another, and, as far as possible, a new location by interchanging is given the returned swarms. This seems to better satisfy them. By the next day (often the next hour), after being returned, the bees are back in the sections; and by the time there is further disposition to swarm, the sections are finished, when they are removed and the upper story filled with combs, for extracting what honey may yet be gathered. If there has been any preparation for swarming at the time of taking off the sections, this is broken up by destroying cells, placing empty combs in the brood-nest, or by any of the many well-known plans of breaking up the disposition to swarm.

This season I did not work for much comb honey, and hereafter I will work for less, as I have a much better demand for extracted honey. From the 56 colonies at my home apiary I got 2000 lbs. of comb honey and 3000 lbs. of extracted honey. I sold 34 three-frame nuclei from those which were formed by taking from full stocks, three frames having the most brood with the adhering bees and queen; this was done during the latter part of the honey-harvest. It lessened my crop of honey somewhat.

HOW AN INVESTMENT OF $40.00 REALIZED $240.00.

Last spring I bought 14 colonies in double-walled L. hives for $40.00. These were moved to within three miles of my place. They were generally weak. Some queens had to be superseded, as they were away past the "flower of their age."

By the time white clover was doing its best, these bees were ready for more room. I gave them a case with four full frames of comb and five frames with starters, which were soon filled and ready for the extractor. From these 14 hives I took 2000 lbs. of extracted honey, which brought me $240.00, and I have the bees left in fine shape for winter—a pretty good investment, I think.

Altogether from the 70 colonies I received 2000 lbs. of comb honey and 5100 lbs. extracted honey, and sold from them 34 three-frame nuclei. All are in prime condition for winter. Every colony has a queen of this season's rearing. My bees are ready for the winter, and all I have done was to make passages through the combs, cover the frames with a piece of woolen carpet, put over this a chaff pillow, open entrances wide, and leave on summer stands. I expect to find them all right next spring; at any rate I would not give ten per cent to have them insured.

My honey was all sold in the short time of four weeks, from the time I began to sell. Comb honey was sold for 18 cts., and an average of 12½ cts. for extracted. Part of the extracted was sold for art purposes; part for medicinal purposes, at 15 cts., and quite a good deal to families for table use, at 12½ cts. per lb., or ten lbs. for an even dollar.

A HONEY-RETAILING WAGON, AND HOW TO SELL.

On our retailing wagon we have a large tin can holding 400 lbs., with honey-gate and scales under this, which makes it convenient for quickly weighing the required amount. A case of comb honey is taken along to sell to people who will not buy any thing else. Some who could not be induced to buy extracted honey were gratuitously supplied with a "mess" "free for nothing;" and by the next time we "came around" there was another customer ready for a "dollar's worth of that strained honey." I can now sell 400 or 500 pounds of extracted honey in one day in some towns where, at first, it took fine talking to sell 50 lbs.

I often wonder why it is that so many of our bee-keepers have so hard a time in selling their honey. True, we are surrounded with many good-sized towns here; but commission men bring to these places great quantities of honey, which is offered low. To convince myself that

HONEY CAN BE SOLD IN ALMOST ANY PLACE,

I loaded up, one morning, 400 lbs. of extracted and 100 lbs. of comb honey, and started right out through the country. Among farmers I sold from 50 cts. to $5.00 worth at almost every farmhouse; and long before night we were home, and honey all sold.

It is at all times necessary to have a *first-class article* of honey to build up the trade. I bought, some years ago, 2 barrels of linden and one barrel of California sage honey, and sold it out on the strength of my reputation; but it was the means of hurting my trade for a long time. Linden and

California sage will do in the comb; but don't offer it in the liquid form, if your object is to establish a market for extracted honey.

JOHN A. BUCHANAN.

Holliday's Cove, W. Va., Nov. 16, 1886.

Friend B., I should say you got a very fair price for your honey during the present season of low prices; but it took some labor and some energy to do it; and, in fact, there is no chance to make progress anywhere, nowadays, without taking pains and trouble. You have given us one of the best illustrations I ever saw, of the possibilities of building up a home market; and I do believe that a convenient peddling-wagon, with a smart man to manage it, is going to prove the outlet for our great crops of honey. I don't quite understand, however, how a good article of linden honey, or a *good article* of California sage honey, has been the means of injuring your trade.

MRS. GLIDDEN AND HER BEES.

WHAT A REAL LOVE FOR A CHOSEN PURSUIT MAY ACCOMPLISH.

ONE pleasant morning, four years ago last spring, a lady came into my office, and, without any particular introduction, said she would like to talk with me a few moments about bees, if I was not otherwise engaged. She was about thirty-five years old, I should judge, and spoke in a pleasant, rapid manner that was quite captivating. I at once gave her attention, and she began to ask questions about bees, hives, etc.—knowing that I was much interested in bee-keeping, and had a few colonies. Somehow, I did not then find out how, she had got an idea that she could keep bees, and she was determined to try. She asked me several questions, and wished to know my opinion about the hive advertised by a Mrs. Cotton, of this State, and about her way of managing bees. I said to her that I thought she did not want the Cotton hive, book, or any thing else from that source; but I advised her to correspond with my good friend Mason, of Mechanic Falls; and if she was fully determined to start an apiary, to start right by getting a Langstroth frame hive, all fitted with sections, etc., and purchase her bees of Brother Mason. She has since thanked me for "starting her right," and giving her good advice. I may say here, before proceeding further, that I had for some years known the lady by sight, and knew her husband as for some time a resident of this city, an estimable man, a carpenter and builder by occupation, who owns two houses here, and whose home is at the corner of Green and Chapel Streets. Well, I loaned Mrs. Glidden some books and bee-journals, and, after a pleasant chat of half an hour, she left.

Soon after this call I learned that Mrs. Glidden had bought a colony of Italians of Brother Mason, and had them safely located in one corner of her little garden. Then she commenced a regular course of reading in bee culture. She read every thing; and as the public library contained no books on the business of bee-keeping, I gladly loaned her from my own collection. In a surprisingly short space of time she had read and mastered Cook, Langstroth, the A B C book, King, Alley, and lately she has read Heddon, and—just think of it!—the whole of Huber. Besides these she has regularly read two or three bee-papers, and is now a subscriber to GLEANINGS, *The American Bee Journal*, and other papers; and she also carries on quite a correspondence with some of the leading bee-keepers in different parts of the country. But, as my good old father used to say, I am "getting ahead of my story." On the 4th of July of that year, the colony purchased of Brother Mason sent out a swarm, and this embraced her entire increase for that season. The two colonies were wintered out of doors, on their summer stands, being packed with leaves, and a tight shingled roof placed over each hive.

The second year, 1884, Mrs. Glidden devoted considerable time to dividing her colonies and rearing queens. This last she undertook because it was interesting, and she would rather rear them than to purchase and pay away money for them. She understood the business perfectly, and succeeded admirably. This year she increased her two colonies—which came through the winter strong—to twelve, making ten new colonies, by dividing. This work was carried on quite extensively, as will be seen, and perhaps some mistakes were made. It would not be strange if there were. She lost two colonies in August or September of that year from lack of stores, as she did not feed early enough in the season. That fall she went into winter quarters—on the summer stands, as before—with ten colonies. Five of these came through the winter, but in the spring of 1885 they were very weak. Mrs. Glidden understood feeding by this time, and they received attention, and built up strong during that season. She did not feed any in the fall; had little surplus honey; but the five colonies of spring had increased to ten strong heavy colonies by fall, and they were, as before, well packed for winter with a protection of leaves, and tight shingled roofs over each hive. Mr. Glidden, although a very busy man, had before this become much interested in the bees himself; and, being a carpenter, he had made all the hives needed, the sections, etc., during odd days in the winter season.

So far in her experience as a bee-keeper, Mrs. Glidden had received but little surplus honey. Indeed, she had not planned for much. Instead, she had been reading, studying, rearing queens, dividing, experimenting, and learning; all being done in a quiet, earnest, determined way, with no thought of being discouraged or giving up the business, or getting tired. She was bound to succeed, and she has.

Last spring Mrs. Glidden's ten colonies of bees were found to be in excellent, strong condition. This season they have just doubled, or increased to twenty. She gave away one colony to a friend, has sold four, and has an even fifteen colonies with which to go into winter quarters. They are a pretty sight, as they stand in uniform rows in the little garden at the corner of Green and Chapel Streets, this city; and many are the visitors Mrs. Glidden has had at her apiary during the past three years. The honey-record from this apiary the present season has been a total of about 1200 pounds. About 300 pounds of this has been box honey, the remainder extracted honey. In June, Mrs. Glidden purchased an extractor, and has used it freely. She has put up her extracted honey in neat one-pound glass jars, with her name on a label on each jar.

This honey she has placed on sale at the leading grocery stores in this city, and in the adjoining city of Hallowell, two miles distant, as well as in the city of Gardiner, six miles distant. From this it will be seen that Mrs. Glidden has a fine local market; and in placing the honey on sale she has made all the contracts ana done all the business herself. For comb honey she receives 20 cts. per pound; and for extracted, one shilling. In addition to her sales at the stores, many come to her house and purchase in large quantities, so that her honey has been in great demand this season, and there is sure to be a greater call for it next year, as this season the prejudice against extracted honey has been overcome, and she now has an assured sale for all she can produce. Her success has been most gratifying, but she deserves it all. Her intelligence, courage, and enthusiasm have the promise of sure reward. But, did you ever think, friend Root, that bees work faster and better, and store more honey for some than for others?

Mrs. Glidden is an earnest worker, and most esteemed member in the church to which she belongs; and she is also a member of Capital Grange, P. of H., this city, and all her brothers aud sisters of the Grange hold her in high esteem as a sister and a friend. Calling at her home a few evenings ago with my wife (she has three fine children, the eldest a young lady of sixteen, a pupil of Cony Academy), I asked her how she first came to be interested in bee-keeping. She replied, that she "always thought honey was nice," and that she "wanted to have some"—a woman's reason. It is nice, as we can attest, as a sample of comb honey made by her bees in June last is certainly the whitest, clearest, and finest-flavored honey I ever ate. SAMUEL L. BOARDMAN.

Augusta, Me., Nov. 11, 1886.

THE MERITS OF ALSIKE CLOVER.

WILL IT PAY FARMERS TO RAISE IT, WITHOUT ANY REFERENCE TO BEE-KEEPING AT ALL?

THE above heading suggests itself to me while reading an article from *The Farmer*, of St. Paul, Minn. The article has not a word in it in regard to alsike for bees. It simply speaks of its value for stock, and for raising seed to sell. As there are some new points in the subject, we make the following extract:

About 20 years ago I bought my first alsike clover seed, and sowed it alone on the south side of a hill. The season was dry, and it grew only about a foot high; and as it was said the first crop produced the seed, I cut it for seed and felt disappointed at getting so little that I was ready to pronounce it a humbug, and plowed it up the same fall. Some years afterward I saw a bushel of seed at the Dane County Fair, at Madison. I inquired of the owner, Mr. Woodward, how he liked it, and if it was a profitable crop. He said he got four bushels of seed per acre, and sold it at $10 per bushel; that the hay, after being hulled, was better than the best red-clover hay, and that his cattle ate it in preference to any other hay. I bought two bushels of the seed and sowed about one bushel to twelve acres, mixing one-third timothy, by measure, where I wanted it for pasture or hay, and about the same quantity of pure alsike where I wanted it for seed. It does not raise seed the same year it is sown, but, like red clover, the next year. I have sown it with wheat, barley, and oats. It does best with spring wheat or barley.

I hulled 110 bushels this year from 20 acres. I expect to get $7.00 per bushel, and I have at least 25 tons of good hay, after hulling, worth enough to pay all expenses of cutting and hulling. Some years ago I sold my whole crop on the Board of Trade in Chicago for $11.00 per bushel.

Mr. George Harding, of Waukesha, a breeder of Cotswold sheep and short-horn cattle, and one of Wisconsin's most wide-awake farmers, showed me a small field of one of his neighbors that he said produced seven bushels of alsike seed per acre, and that he sold it in Milwaukee for $12.00 per bushel. I have 80 acres in alsike; and so long as it pays me as well as it has done, I will sow it.

The first crop the next year after sowing is the seed crop. It can be cut for seed for several years. It is not a biennial plant like red clover, but a perennial. It has one tap root with many branches, and does not heave up by frost, like red clover, which has but one tap root.

I prefer it to red clover for several reasons. When sown with timothy it matures with timothy. (Medium red clover matures before timothy is fit to cut.) I cut about the 10th to 15th of July; red clover should be cut (here) about the 20th of June. Alsike is not easily injured by dew or light rains after being cut. It has none of the "fuzz" that red clover has, making it so unpleasant to handle as hay or seed. The stem is not so coarse nor so hollow, and has more branches, leaves, and blossoms. The blossom is of a pink color. Red clover must be cut when we are in the busiest time working our corn. Alsike is cut after corn work is over. This is of great advantage in a corn region.

Alsike makes a good fall pasture after the seed is cut. My stock will eat it in preference to red clover, timothy, or blue grass. Blue grass, or, as it is often called in this country, June grass, is a good early and late grass, but in midsummer it dries up; and had it not been for clover we should have been badly off for pasture this dry year.

HON. MATT. ANDERSON, Dane Co., Wis.

PRESENTING BEE CULTURE IN TOO "ROSY" COLORS.

WHAT IS THE OUTLOOK?

BELOW we have made a few extracts from the reply of the editor of the *Canadian Bee Journal* to an article headed, "What Is the Outlook?" The writer of the article spoke of the recent bad seasons and the low prices, and the general discouragement of many bee-keepers. The editor answers:

We will not for one moment question the assertion that bee-keeping may have keen painted "in its most rosy colors," possibly in some cases too much so; but almost any one will admit that there were good reasons for appropriating the "paint" to that purpose. Bee-keeping then *was* a business in which there was much profit and little loss—proportionally speaking. The principal trouble now seems to be the disposal of the crop at a fairly remunerative price. Bee-keeping is now down to a business level, while it formerly was a special pursuit; with extra advantages, of course there will be lots of bee-keepers disgusted, just as there were lots of store-keepers disgusted with *that* line when they found that "sitting on a nail-keg" in their store was not going to give them a living. Since bee-keeping has taken a legitimate stand amongst other branches in the commerce of the country, neither writers nor supply-dealers have to any extent painted it in "colors" others than of which it was deserving. There are, even at the present price of honey, large profits in successful years, while in poorer years the profits are not so large. It must be admitted, that during the past four years there has not been much above an average yield; but "depression" is the cry in almost every department of the commerce of the country, and bee-keepers can not always expect unexceptional favors. The little couplet which is often used with reference to poets is applicable as well to bee-keepers:

"Not every man can be a poet,
No more'n a sheep can be a goat."

I would especially emphasize the point about sitting on a nail-keg. There may be seasons and opportunities when a man can lay up money and sit still, and rest a great part of the time; but such things do not occur often, nor do they last long, and I think it is a wise provision of Providence that such is the case. The world is full of tradesmen who can not make a living, or who succeed in making only a very poor living; and I believe it is often the case, that the sole reason of this is, because they don't get up and make things go. It has been many times intimated, that the supply-dealers are the lucky ones in our chosen pursuit; but I tell you, my friends, there are about as many supply-dealers who fail, as there are honey-raisers. To succeed in any industry, one must not only work all day, but he must use his brains in the night time, and after the labors of the day are past. He must carve out his fortune by hard work and hard knocks. When seasons are poor and prices are low, he must economize and cut down out-goes, and he must learn to do it until he comes clear down to hard-pan. When he learns to weather the storms he will probably be ready to make hay when the sun shines. Sitting on a nail-keg will never build up a business anywhere.

A MODEL KITCHEN.

PROF. COOK TELLS US SOMETHING ABOUT THE CONVENIENCES OF THEIR OWN KITCHEN.

I READ with much interest Mr. Terry's description of his bath-tub. Such articles are *good seed*, which may not lodge in soil to always take root; but when they do produce they bear such excellent fruit that they are always opportune.

Now, Mr. Editor, our house was already built, and there was no available room over the kitchen or elsewhere to be used exclusively as a bath-room. I presume there are many other such homes. We —wife and I—are *full* partners, and we concluded to make our kitchen the bath-room, especially as we could at the same time greatly increase its conveniencies in other respects. Let me say, that I married one of those very girls that Mrs. Chaddock writes about. This wife, except when we have company, does her own housework. She prefers this. The work is far better and more economically done. We all enjoy having our home wholly to ourselves, except in times of company; and then, again, it gives opportunity to give our two children useful work. Katie, only eleven years old, makes all of one kind of our bread, and most of the cake. By the way, she took the premium on bread at our fair. The children do their own room work, wash the dishes—and, more, are most happy doing this, "*if we can only be without* the *girl*."

Thus it is that we desire to have our kitchen as pleasant and as neat, and the *most convenient* room in the house. The room is 12 x 14 feet, has windows on both ends, is neatly carpeted, and we think it is as cozy as need be. The bath-tub, which cost us twelve dollars, is at one end of the room, in front of two windows. I cased it about with oak, neatly matched, and covered all with a hinged cover of beautiful cherry wood, which shows nature's beautiful graining to perfection. The cover of this is held up by a catch when we wish it up. The escape-pipe runs to the same drain which carries off the house-slops, and thus this drain is flushed every time the tub is used, and, indeed, every time we wash, as will be seen. It seems to me that every house should have such a drain if possible. Health and convenience demand it. Neatness certainly emphasizes the argument; for what is more repellent than the horrible cess-pools seen back of so many country homes? When the cover is raised, a board across the bath-tub lengthwise makes just the right wash-tub bench. Each tub has a hole through the bottom, with a rubber-stop; so to empty the tubs on washday, one has only to raise or withdraw the stop. As a rubber hose may be made to connect from the cistern pump, which is a force-pump, to tubs on bath-tub, or to boiler on the stove, it will be seen that a whole washing may be done without lifting any water except to empty the boiler. When the cover of the bath-tub is down it makes an excellent kitchen table, and also serves as an ironing-table. If desired, we may stop right here. But *we* have added about $50.00 more, and have added hot-water works. As the tank in the bedroom above, which serves as a stand, holds about three barrels, and as I each morning fill this, which takes about fifty strokes of the pump, wife never has to pump or carry any water to do her work. What better planning can be done in any home, than planning to save work for the *queen* of the home?

Each door of the kitchen has an inside lock, and all the windows have shades, and so the use of the bath-tub may be as private as though it were kept in a special room.

One more convenience that gives us nearly as much satisfaction as does the bath-tub, is a frame to hang clothes on, which is fixed to the side of the room opposite the sink, stove, and wood-shed door. This is simply a light square frame like a slate frame, made of ash, and is four by seven feet in dimensions. A cross-bar in the center strengthens this frame. Through the end and center bars, holes are bored, and a common clothes-line is stretched lengthwise across the frame every five inches. This is a "*roped*" frame, not a "wired" one. Two strap hinges fasten the bottom of the end-bars to the wall, about four or five feet from the floor, while a small chain is fastened to the top of the end-bar, and then passes over a small pulley screwed into the wall just above where the upper end of the center-bar will be when the frame is close against the wall. By use of this chain the clothes-bar can be drawn close against the wall, or let down at any angle. Thus this is always ready for clothes, and is always out of the way when not needed. It is a *suspended*, if not a "reversible frame," for the *kitchen*.

If this article shall induce such action as will lessen the burden of any wife and mother, how glad I shall be that I wrote it! It is near Christmas; and what a nice Christmas present would such arrangements be for many a loving wife, whose work is hard!

I forgot to say, that a neat wood-box stands opposite the bath-tub, which *Bertie* is expected to keep full.

A. J. COOK.

Agricultural College, Mich.

Friend Cook, I have got you and friend Terry on the very topic that pleases me; namely, planning for the *queens* of our *homes*. If there is any department in life where we need kind hearts and earnest thought, it is in lessening the labors of the home. My wife, like Mrs. Cook, has always had a preference for doing her own work; and I tell you, friends, we can afford to spend quite a little money in the way of making fuel, light, water, and air, convenient in the kitchen rather than to go to the expense of hiring a girl to do the housework. In our own home we are now talking about making steam pump the water, and warm it at the same time, by means of one of the cheap injectors now in the market. I tell you, there is no Christmas present that can be studied up that will begin to compare with household conveniences that are *real helps* to the good wife, and not a hindrance.

QUEENS IN TRAPS.

HOW LONG WILL A QUEEN LIVE IN THE UPSTAIRS PART OF THE ALLEY DRONE-TRAP?

AFTER Ernest told of his talk with me about queens of swarming colonies being caught in Alley's drone-traps, Mr. Alley wrote me that Ernest was in error as to the length of time a queen would stay in the trap. I replied that we had in mind a queen remaining and living in the trap, and said, "A queen could hardly live 2 hours in the trap, if the hot sun were shining on it." To this he replied, "Allow me to say, friend M., that you are giving your opinion about that you know nothing about, when you say, 'A queen could hardly live 2 hours in the trap, if the hot sun were shining on it.' I say, the queen will live several weeks in the trap, sun or no sun."

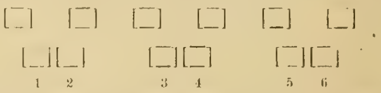
My first thought was, "Yes, I do know what I am talking about, for haven't I had them die in the hot sun?" But, come to think of it, I don't know that I ever did have one die in the sun, where the bees had access to her, but only under a glass tumbler, which would be much hotter than in a trap where the air would have free circulation. I presume Mr. Alley knows what he is talking about, from actual experience; and if so, it is quite important to know the fact, for all that is necessary will be to shut the little opening left for the queen to return to the hive, and then the trap can be looked at once a week. Is there any advantage in any case in having the trap so arranged as to allow the return of the queen into the hive?

BALLING QUEENS.

Referring to the discussion on page 853, I may say I have had considerable experience as to bees balling their own queen. In the spring I go through all my hives, and see whether queens are clipped; and if any are not clipped, I clip them. If, after clipping, a queen is accidentally dropped on the top of the frames so as to fall on the bottom-board at the entrance of the hive, she is very likely balled; and if the hive is at once closed up she may be released, but is sometimes killed. If a queen is placed on one of the combs, right among the bees, she is not likely to be molested. Sometimes, however, on opening a hive the first I see of a queen is to find her balled before I have touched her. In such case, if I close up the hive immediately, and do not open it again for several hours, I am pretty sure to find her all right. Is it not possible that, in this case, the bees ball their queen for the sake of protecting her?

SPACING HIVES.

You suggest, friend Root, that many queens are lost because hives are exactly alike, and too close together. The remedy in such case would be to move the hives further apart. Let me suggest, that a better remedy is to put the hives nearer together —that is, move every alternate hive close to its neighbor. Suppose, for example, 6 hives stand in a row, each hive 18 inches in width, and a space of 11 inches between each two hives. In such case there is danger of bees getting into the wrong hive, except the hive at each end, allowing that there are no trees or other objects by which the location of the hive may be marked. Now move the second hive within two inches of the 1st; the 4th within two inches of the 3d; and the 6th within two inches of the 5th, and you have the hives in pairs, with a space of 20 inches between the pairs.



In the above, the upper row shows the hives before moving, 11 inches apart. The lower row shows them after each alternate hive has been moved within 2 inches of its neighbor, leaving the different pairs 20 inches apart. As before suggested, in the upper row Nos. 1 and 6 appear different from all the others, and no bee of 1 or 6 is likely to get into any other hive; neither is a bee of any other hive likely to get into 1 or 6. But as between the other four hives, there is nothing to distinguish the one from the other, except the difference in distance from side to side; and a bee accustomed to enter its hive at a certain spot will find another spot of exactly the same appearance by going 29 inches either to the right or the left. Generally speaking, that 29 inches is sufficient, but I believe not always; and if a young queen, on the return from her wedding-trip, were not able to identify her own hive where the distance between the hives is only 11 inches, the consequence might be disastrous. But in the lower row there is no danger of a bee mistaking the next hive for its own. A bee of No. 3, for instance, knows its hive as the left one of a pair; and at whatever point it is accustomed to enter its hive, it can find a point similar in appearance only by going a distance of 58 inches to No. 1, or to No. 5. An experience of years in thus placing hives in pairs convinces me that it is important and useful, allowing the hives to occupy much less ground without danger of bees entering wrong hives.

C. C. MILLER.

Marengo, Ill., Nov., 1886.

Our friend Mr. Alley has had a large experience with the trap bearing his name, and I suppose he ought to know whereof he speaks. I may be in error as to the length of time a queen will live confined in the upper part of the drone-trap. I stated in answer to you, that I *thought* the "queen would live four or five hours, possibly a day." As I could not say from experience, I so stated it. We had one queen die in the "upstairs" part of the cage where she was unable to make her escape. No one was on hand at the time the swarm issued; but the fact remains, that the queen was found dead in the upper part of the trap. I can not say just how long the queen was confined there before she died, but it could not have been over a day, and the probabilities are that she died in a few hours. In all other cases, when a swarm issued, when a trap was attached to the entrance, we were present, and the queen, if she did not get back into the hive, was put back before or after the swarm returned. I can not say, therefore, that the instance I have mentioned would be an exception to the general rule, or whether it might not occur more often. I will try to experiment upon this point next season. ERNEST.

Thanks for your suggestions, friend M. I have for a long time been aware that bees would not miss their location when two hives were close together; and the same idea was once extensively used by making two hives in one, with the entrances pointing in opposite directions. In this case the thickness of a single board is all that separates one hive from another. I believe this plan was abandoned, however, because it so often happened we wanted to move one hive away and leave the other in its place. The reason why the hexagonal apiary was planned for only one hive by itself was because I so often found it convenient to be able to walk clear around any hive. Since then, however, we have seen bees make mistakes so much in the hexagonal apiary, we feel like reconsidering this plan. Only yesterday, Nov. 24, it being a warm day, the bees started out of a good many of the hives, and in a great many places quite a little handful of bees were clustering on the side of some other hive where there was no entrance. After investigating a little I found they were mistaking it for their own hive, 14 feet away. Sometimes it does not do any harm for bees to get into the wrong hive during warm spells in winter; but there are times when it may not only result in balling queens, but in the loss of the queen. I should like to have the friends tell us how general it is to find the bees mistaking their location where hives are made exactly alike, as mentioned above.

SEPARATORS OR NO SEPARATORS.

FRIEND DOOLITTLE AGREES WITH THE A B C BOOK, THAT WE CAN NOT DISCARD SEPARATORS.

As the time has now come to begin preparations for another season, the matter of separators or no separators must come up for the decision of each one. Many claim, and have so claimed for the past four or five years, that separators are useless, and, wishing not to appear "wedded to my fixtures," I have tried dispensing with them in a part of my apiary, and actually found that I could, by taking great precaution, as to the hive being level, the foundation being fastened to the sides and top of the section securely, and by giving just the right amount of room, so that the bees would commence in all at once, get combs built true enough to crate, especially if care was taken in crating, so that the "fat" side of one section was placed next to the "lean" side of the one next to it; but when it came to the glassing of them, that was out of the question. To be sure, most markets do not desire glass on the honey; but as a few do, it makes it very handy to have our honey so we can glass it if we wish. While, as I said, I had succeeded by using much precaution in getting a fair job done without separators, yet I found that this same precaution cost me more than the separators; and that, unless I used that precaution, the loss by bulged and unevenly filled sections was still greater than the first. So I concluded that there was nothing gained in trying to dispense with separators, but, on the contrary, such a trial would be very likely to result in a loss, owing to the nicety of the work required. Again, I found that I must leave the case of sections on the hive till finished, before they were disturbed; for if I added more room, except by way of a full case, on the tiering-up plan, I was sure of getting the combs so badly bulged that I could do nothing with them, save to sell them as "chunk honey." This spoiled one of the best ideas I know of in bee-keeping; namely, the putting-on of a small amount of surplus room at first, and gradually increasing it as the bees became strong, until the full capacity of the hive was reached. I am confident that this one idea has had much to do with the success I have attained in producing comb honey; so if I dispensed with separators I lost quite a share of my success also, and all for the sake of trying to do something that somebody else said we must do; "for," said they, "separators are rapidly becoming things of the past." Once more, I could not take my sections off once a week, as I had formerly done, while the combs had a snowy whiteness, which gave my honey a good name in market, but must leave them on the hive till the nice white comb was all travel-stained by the bees; for as sure as I took a comb out and put an empty section in its place, the combs in the sections next to it would have their cells so lengthened that they could not be crated at all. Then each section must be filled with foundation, if I would succeed, no matter how short I was of cash to purchase it. To be sure, I did succeed tolerably well by putting strips of foundation two inches wide in the two outside tier of sections; then 1½ inches wide in the next two tier inside of them, then one inch wide next; and in the center, two tier foundation, only ½ inch wide; but all this required a nicety that was much greater than the use of separators demanded. From the above it will be seen that I have given the non-separator business a fair trial, and was at last driven to the conclusion that, for me, separators are an actual necessity, if I would secure the most comb honey in the best marketable shape.

Not long ago I was reading, when (in 1881) the question was asked through one of our most prominent bee-papers, "Will all bee-keepers agree that it is more profitable to dispense with them (separators) than to keep them?" to which one of our noted writers replied, "It is not at all likely that *all* bee-keepers will, as some are so wedded to their fixtures and methods that it would be almost impossible to induce them to even *try* some better method;" and yet, if I am correctly informed, that noted writer has left that "better method" (non-separators) and gone back to using separators again. Would it not have been just as well to have known for a certainty of that "better method" before such a "hue and cry" was raised against one of the best combinations (wide frames with separators) which we have in the line of apicultural helps. Some have thought that separators cost them considerable of their crop of honey;

but from careful observation for the past 14 years, I fail to find any thing pointing toward such a conclusion; but if any really feel that such is the case, Mr. Betsinger's new wire-cloth separators will remove all such objections.

Why I have written this is because I believe we have been trying to make a move in the wrong direction by this non-separator business; and I hope all will take an interest in seeing that good prices in our markets can be maintained only by putting upon it that which is as nearly perfect as possible. G. M. DOOLITTLE.

Borodino, N. Y.

"THERE IS LOTS OF HUMAN NATURE IN FOLKS."

MRS. CHADDOCK'S OPINION OF HUMANITY.

YES, that is so. We like people better after getting acquainted—*with some exceptions.* I know people like me a good deal better than they used to. Twenty-three years ago I was a schoolteacher and book-agent combined, and folks didn't seem to like me very well. Their affection for me was of the mild type that doesn't make a man lay down his life for a friend. In company with a girl-friend I canvassed most of the time during vacation, and I thought then that folks were *unnecessarily cool* toward book-agents, though at some houses we were *too* warmly received—the women giving us a piece of their minds, and one man said he would set the dogs on us if we came inside his yard. I lived through it all. About fifteen years ago people began coming to me to apologize for the way they talked to me when I used to sell books, and they keep on coming. Only last week I met a woman in a store, and she said she wanted a little private conversation with me; and when we were alone she said, "I want to ask your pardon for the way I treated you over twenty years ago when you came to our house selling books. I was ashamed of it as soon as you were gone, and I've been ashamed ever since, and have often thought of telling you so, but could never get up courage enough. I hope you will forgive me."

"I do," said I; "I forgave you long ago."

"Oh! then perhaps you did not care much for what I said," said she.

"Yes, I did," said I; "I cared a great deal; so much, that I laid awake and cried all night about it."

"Well, I'm sorry," said she; "and I didn't mean what I said; I just got started, and you seemed so astonished that I felt encouraged, and said all I thought, and a good deal more."

But the man with the dogs made the most abject apology of all. He waited only ten years, and he was humble enough to eat fried grass. I forgave him. Then about two years ago a woman said to me that she served me a mean trick once. She said that once when I wanted their school, and her husband was school-director, and was going to hire me, she would not let him; she said she guessed she pretty nearly told him a lie to keep him from hiring me, and she had felt sorry about it almost ever since. One thing that made her sorry was, that the teacher they hired was a *poor excuse*, and they turned him off, and the children had to stay at home all the rest of the winter. Then she said she felt bad about the way she had treated me, and sent her husband the next winter to hire me; but I had a school somewhere else, and she had not seen me very often since. I told her that I wished she had not told me. She said she *had* to tell me; that she had got religion a short time before, and she was going to own up to everybody all the mean things she had ever done to them. There's lots of human nature in folks; and if we all live long enough every thing will be straightened out, I suppose; but with my impatient disposition I can't see why folks will go on, year after year, with their consciences on the rack, when a few words will end it all. And I am very sure that I like folks better than I used to. I like all the folks in the world better, and I take more time to get acquainted with the people I meet. When I used to work in the fields all day, and do my washing and baking after night, and before daylight, I was cross and selfish, and it tired me to talk to folks. I thought I was smarter than they, and that they were not worth wasting time on. But I've found out, of late years, since I've had time to listen, that almost everybody knows something, "specially beekeepers," and it keeps me busy trimming my lamp and pouring in oil, not to be entirely extinguished by some of them. MAHALA B. CHADDOCK.

Vermont, Ill.

It seems to me that one moral to your little story, my good friend, is, that book-agents are not needed in any community; and I do not believe I would ever encourage any kind of business which brought the ill will of so many good people, then the necessity of such apologies as you mention would have been spared. It is well enough to peddle honey that you raised at your own home; but book-agents and book-peddlers are so universally recognized as nuisances that it seems to me that we had better give up that kind of business.

CALIFORNIA.

BY ONE WHO IS ENTHUSIASTIC OVER THE RESOURCES OF THE COUNTRY.

FRIEND ROOT:—Should you come to Pasadena, Cal., in early spring, as I did, you would have to confess that neither tongue nor pen could give you an idea of the loveliness of the place. I left Gambier, O., April 5. There was six inches of snow on the ground; weather was cold, and was snowing hard. We were snowed in at Chicago for 5 hours the night I left home. After eight days of varied cool and snowy weather, imagine, if you can, what it is to suddenly drop down, as it were, off the mountains into the San Gabriel Valley one afternoon, where every thing is green, and see the orange-trees hanging laden with golden fruit, with their dark-green foliage, and their waxy blossoms filling the air with their fragrance, mingled with that of the calla-lilies.

I came here to go into the bee-business in Southern California. I have not done much at it yet—not because I did not find that business as good as I expected, but because I found other businesses so much better than I expected. Nice white-sage extracted honey is retailing here at 5 cts. per lb.; white 1-lb. sections are selling at 10 cts. Bees are almost idle now, as this is their vacation, with their hives so full and heavy as to be not easily lifted.

Where the honey has not been extracted, I believe this has been considered a very good honey year, although I have been too busy to gather much in regard to the business. I believe San Diego is the great honey-region of California, while Pasadena excels in fruit and beautiful homes.

I have worked up to date, since I have been in Pasadena, 157 days. I have not worked one day for less than $3.00 per day, and I am at present getting $3.50 per day in gold, every Saturday night. My boss won't employ any man who uses tobacco, drinks liquor, or swears, so, you see, I have good company to work in, and might be expected to have a good time. I am a journeyman carpenter. I believe all occupations pertaining to the construction of houses, or building up a city, have paid as well as carpenter's work.

Now, just one word about Pasadena. It is a new place, and one can't find such a thing as a dilapidated house, barn, or fence. The buildings are all new, and some are of the finest architecture. The buildings are mostly wooden—Oregon pine for the frame, and California redwood for finishing. Lumber can be obtained here of almost any length, up to 60 or 80 ft. Selected redwood makes the finest finish of any soft wood I ever saw.

There are some people who come here and don't like the place (chronic growlers), and I do believe there are many who, if transported to heaven, would not like it any better, because the associations would not be the class they were used to.

I used to hear of an occasional earthquake in California; but after spending 7 months here, where every day is as calm as June, and reading about the awful earthquakes and cyclones and floods they are having in the East and South, I just thank God that I am in California, and wish that many of the suffering ones were here too. Let me just say, that I am not interested, more than any other good citizen.

Pasadena, Cal., Nov. 8, 1886. H. H. HILLIER.

THE HONEY-BOARD.

OLD-FOGY JUDGES.

I EXPERIENCE a great deal of trouble with honey-boards. I have the enameled cloth, but I want a board that will hold itself up so I can put on boxes for honey, holding 10 or 15 lbs. each, without foundation. Such packages sell much the best in this section. I have never used the zinc. Will that be the best thing I can get? I see in GLEANINGS, Oct. 15, page 814, something said about the Heddon and Tinker honey-boards. I should like to know where I can find a description of those boards. I take GLEANINGS, and have the A B C book. What do you use for a honey-board? I glued wooden strips on the top of some of my enameled cloths, ¼×½ inch, and ½ inch apart, that kept the cloth up all right, and worked first rate to cover the frames; but I can't use that to set my boxes on, that I can see. I could use the old wooden boards with holes through them; but I do not like them to remove from over the frames, for they are quite apt to take the frames along with them, with me. I should like to know what you would use if you were in my place. If zinc were to be used, I should think the bees would be likely to stick both to the boxes and frames, and when taken off would bend and spoil the zinc (perhaps not).

I must tell you of one of my experiments with the honey-boards. One of our best bee-keepers in this State uses the old-style honey-board in two pieces. The thought struck me, that if two were better than one, why four would not be better than two, so I had enough made to cover 12 hives; but I at last took the precaution to try but one at first, and that proved enough; so when I wanted to remove it to put on the cushions for winter I commenced and took off the first and then the second, and the third; but by this time there was a good deal of a rumpus, and off came the fourth, and with it, not all the bees in the hive, but enough to completely cover my hands and wrists; and when I got them shaken off, my hands looked as though they had got nicely pin-feathered, the stings were so thick; and I found more real sharp points in that experiment than in any other I ever made with bees. I can stand a dozen or so bee-stings; but when they come by the hundreds I can't say I like it very much.

I want to use those large boxes, for the reason that our people here in Vermont do not like to buy honey in such small packages as 1-lb. sections, or even 2-lb. Those who are able to buy honey at all, want it in from 5 to 20 lb. packages. They seem to feel as though they had got enough to last them over night, and it is so with other things they buy—sugar by the 100 lbs., flour by the barrel, beef by the 100 lbs., whole hog, etc. Our bee-men here who had their honey in such boxes as I mention, this year could not supply the demand, even at 20c. per lb.; while my honey, in clean white 1-lb. sections, went begging for a buyer at 15c., and then they would turn them over several times to see if every cell was perfect, and then take it, only for the reason they could get no other. Before leaving they were apt to ask if the comb was artificial or pure, and what I fed my bees on, etc.

MORE "BOODLE" IN RENDERING DECISIONS ON HONEY AT FAIRS.

I took two packing-cases, full of my best 1-lb. sections, to our county fair this fall. There were two other lots besides mine—one an old 15 or 20 lb. box with round holes in the sides, and pieces of glass tacked over those holes on the inside. I should judge it had been used a dozen times or more. The next lot was in a little later style. I stood at a little distance when the committee came around. They first came to the old box, looked it over carefully, took off the cover, smelled and tasted of it; did the same with the next lot, then came to mine, held a section up to the light to look through it; smelled it; made some low remarks to themselves, and passed on. The result was, the old box drew the first, and the next the second prize, and mine not noticed. I learned afterward that the committee were told that the comb in my sections was made by machinery, and was not made of beeswax either, and that they were filled with sugar that was fed to the bees.

I think now I shall get some of the old boxes my father used over 50 years ago, and have them filled ready for the county fair next fall; and I feel very much as though I should like to be present and stick the committee's noses into one of the old boxes up to their eyes, so they could see and smell at the same time.

The 1-lb. of bees I got from you last spring did first rate, and are now as good a swarm as I have.

Moscow, Vt., Nov. 15, 1886. J. W. SMITH.

Why, friend S., your letter is really refreshing. We have not had any thing like it for a long time; but if you will take my advice you will not go back to those old-fashioned things in too much of a hurry. By the time you would get rigged with your honey-boards and big boxes, the committee would get educated, or they would have a different one, and then you would be left out in the cold again. Why did you not walk up to that committee and tell them that the honey was just as pure and good as that in the old boxes? Show them an A B C book, and some copies of the bee-journals.—If your people want a 20-lb. box, why not give them a case full of sections? It will be almost as cheap for you, and I am quite certain that very soon they would outsell the old traps you mention.—You will find pictures of the honey-boards on pages 47, 121, and 771, for the year 1885, and 373 and 613, for the past year. I think the honey-boards made of strips of wood, alternating with strips of zinc, will be the best thing for your purpose. These are made especially to avoid the bridge-combs that attach them to the brood-frames and honey-boxes. The hives we send out don't need any honey-board at all; and if anybody wants a whole box of honey you can sell the case of sections with it, just as it comes off from the hive; and I think any tidy housewife will prefer a box of honey so arranged that each comb can be lifted out without dripping and daubing.

SUGGESTIONS IN REGARD TO FOUL BROOD.

THE PHENOL, OR CARBOLIC-ACID TREATMENT, AS TRIED BY ROBERT SPROULE, OF IRELAND.

DEAR SIR:—I am sorry to see, by GLEANINGS, that you have foul brood in your apiary; and as you do not seem to have any faith in the phenol treatment, I trust you will accord me space to say a few words in its favor, premising that my knowledge of the disease is limited to what might be gained by observations with the naked eye, and while endeavoring to eradicate it in an apiary of half a dozen colonies. The scientific aspect of the question I leave to those whose skill and training enable them to investigate it, and I accept their statements, in so far as they agree with my own experience, as being made in good faith for the general good.

Up to a few years ago it was generally supposed that there were two distinct forms of foul brood—the "virulent" and the "mild," the difference being that the first was difficult if not impossible to cure, while the second gave way to systematic treatment, and sometimes disappeared without any special treatment. Beyond this, nothing was known of the disease; and as to a remedy for the "virulent" form, I say, without hesitation, that there was none, the alleged cures by means of salicylic acid to the contrary notwithstanding. Recent discoveries have enabled us to distinguish between both forms of the disease, and to cure one almost as easily as the other.

I first saw foul brood about eight years ago, when it appeared in my apiary in a colony of Ligurian bees, to which I mangaged to confine it by spraying with salcylic-acid solution and other treatment until the following summer, by which time every colony I had was infected. For the next three or four years I was unremitting in my efforts to stamp out the disease, but without success. During all this time my bees never swarmed, and I was obliged to destroy dozens of combs by burying them in the earth, and all to no purpose. The bees formed queen-cells, but the contained grubs died immediately after sealing over, and I was obliged, each season, to buy swarms and driven bees in order to keep up my stock. Matters went on in this way until the autumn of 1882, when a friend suggested carbolic acid as being worth a trial; and as I could not be more unsuccessful with it than with salicylic acid, I determined to act on the suggestion. At this time I had four colonies, made up of driven bees hived on full sheets of comb foundation, and fed with sugar syrup, in which salicylic-acid solution was mixed. As I had not made up my mind as to the best way to give the carbolic acid to the bees, my intention was to leave them alone until the following spring, by which time I would have fixed on a plan of operations.

The next step was to find out the make of carbolic acid best suited for my purpose; and after a good many samples had been tried I concluded that what is known here as "Calvert's carbolic crystals, No. 1, B. P.," would be most easily administered, as it was soluble, even in cold water; and its taste, when diluted and mixed in syrup, was not disagreeable. I prepared it for use by melting the contents of an ounce bottle and pouring into a quart of cold water, which was shaken up until the crystals were dissolved, after which the bottle was corked, and I considered the solution ready for use. The following spring I took a look at my four colonies, and found them badly diseased. Brood-rearing seemed to have been going on very briskly, and the bees were much reduced in numbers. There were very few, if any, healthy cells in the brood combs; and after a little consideration I concluded that the remaining bees were not worth saving, and I determined to give up keeping bees for that season, and to make a fresh start the following one, with new hives and other gear, so as to avoid any further risk of disease. I took no trouble with the diseased colonies beyond placing an inverted tumbler filled with syrup, in which, for curiosity's sake, I mixed some carbolic solution near the hives. The bees took the medicated syrup readily, and the tumbler was refilled as required. Not being at home during the daytime I saw very little of the bees, and, in point of fact, I took no interest in them; and so when, on my arrival in the evening, I was told that "the bees were flying very strongly to-day," I merely smiled, with the air of one for whom the pleasures of bee-keeping had long since passed away, like all other pleasures of our imperfect existence. This state of indifference continued till one warm morning about the end of May, when I happened to pass in front of the hives just before leaving for the city, and was astonished at the activity of the bees. At the first opportunity afterward I opened and examined the hives, and found that all traces of foul brood had disappeared. The combs had been cleaned out, and were now filled with healthy brood and drone-brood capped. Before the end of June each colony gave a swarm, and, better still, the queens hatched out in every case. Those very satisfactory results seemed to me so important that I lost no time in placing the facts before the greatest living authority on scientific bee culture, Mr. F. Cheshire, who said the treatment was quite new to him. He promised to make experiments with the carbolic-acid remedy, and, if successful, to give the results to the bee-keeping world. As a test, a diseased colony was selected and marked for identification, after which it was placed in Mr. Cheshire's care. A couple of months afterward it was examined by competent judges, who pronounced it healthy, and without the slightest trace of foul brood. Mr. Cheshire gave a very minute description of this disease, as well as directions for its cure, in a paper which he read at a meeting of the British Bee Association; and this paper, which caused a good deal of sensation at the time, was reproduced in several of the American bee-papers. In the course of his investigations Mr. Cheshire discovered that the statement, so often and so confidently made, that the queen does not carry the infection, is misleading, as he found the bacillus of foul brood in the ovaries of several of the queens he dissected in the course of his investigations. To my mind, this discovery proves that, to destroy foul brood in a colony having one of these diseased queens, her removal and the substitution of a healthy queen should be the first step, after which the rest is easy.

To return to my own case: In the month of July I gave Ligurian queens to three of the four colonies, the other having a black queen just beginning to lay. All went merry as a marriage-bell until the time came to feed up for the winter, when I was concerned to find that the Ligurian bees would not touch syrup if it contained the least trace of carbolic acid, while the blacks took it without hesitation. In the hope of compelling them to take it, I allowed them to run almost to the starvation-point; but in the end I was obliged to give them unmedicated syrup, which they took freely. About the middle of November I examined the four colonies, and found the Ligurians had foul brood badly, and were very weak, while the blacks were strong and perfectly healthy, and without the least unpleasant smell. In the following February one of the Ligurian colonies was dead, while the others were reduced to a mere handful of bees; and as they were not amenable to remedial treatment, I allowed them to die out too, after which I sprayed the combs with carbolic solution, and disinfected the hives with the apparatus I described a short time since in GLEANINGS. The black colony came out of winter quarters strong in bees, and since then I have not had any trace of foul brood in my apiary. I attribute the outbreak of the disease in the Ligurian colonies to my not having disinfected the hives, which were those in which diseased colonies had previously wintered.

The foregoing account is written from memory, and on that account may seem open to objection. When I began treating my bees for the disease with salicylic acid I kept an accurate note of every thing I did; but three years of unvarying failure so discouraged me that I looked on taking notes as pure waste of ink, not to speak of time and paper. Besides, when I began the carbolic-acid treatment I had no hope of being successful, and consequently took very little interest in the matter.

My recommendations to you would be remove the queens of all your infected colonies, and to hand them over for instant execution to the common hangman. In their places I would introduce queens reared in some apiary free from any suspicion of disease. A number of outdoor feeders should be filled with honey or syrup; and when the bees begin to feed freely, phenol (carbolic acid) should be added in small but increasing doses, until the dose is as strong as the bees will take it. I recommend outdoor feeding, because I have found that bees will often take feed that way when they would not touch it if offered to them in the hives. If this treatment is pursued systematically, I venture to say that, before next summer, you will be rid of foul brood.

Your plan of disinfecting hives by means of a jet of high-pressure steam, I think a capital one, without prejudice to my own apparatus for the same purpose which was intended for that large and deserving class of bee-keepers who don't happen to have steam-boilers at command.

Nov., 1886. ROBERT SPROULE.

Richmond Road, Fairview, Co. Dublin, Ireland.

Thanks, friend Sproule, for the results of your experiments with the phenol, or carbolic-acid, treatment. From our experience with the phase of the disease which has visited us, we can not think that the queen gives the disease. Of the sixty cases of foul brood in our apiary, her majesty was retained in all, after we had treated the colonies as we have before described. In not one has the disease reappeared. Surely, then, the queen would have given the disease, at least in a few instances, if it were possible. It may be, that the most advanced stages of foul brood might affect the queen, for we have not allowed a colony to be diseased long in our apiary.

THE NEW HEDDON HIVE.

FRIEND HUTCHINSON,S REPORT IN REGARD TO IT.

I PRESUME many will be pleased to know what I think of the new Heddon hive, now that I have used it two years. I think of it exactly as I did when Mr. Heddon first explained to me its construction and advantages. I lay no claims to superior wisdom; but when a man has studied and practiced bee culture, working with his whole heart in the business, and with wits sharpened by the fact that he *must* succeed or wife and babies will go hungry or cold; I say, when a man has worked this way for ten years, as I have done, he can form a very nearly correct opinion of any new feature in bee-keeping without even trying it. There are, however, "weak spots" in the best of inventions, defects that even the brightest and most experienced fail to discern, and that nothing short of actual trial will point out. It was these "weak spots" that I feared in the "new hive;" that I have watched for with the closest of scrutiny; and the nearest approach to one that I have found is the use of compression for holding the frames in position when inverted. As I learned how to manage, however, I had less and less trouble, and I think I shall have none hereafter.

I find that inverting will do all that has been claimed for it—secure frames full of combs; clear the brood-nest of honey; hasten the completion of sections, enable us to rear large quantities of brood in a comparatively small hive, and to choose whether we shall have brood-chambers full of honey at the end of the season, or the opposite.

I have learned, though, that alternating the horizontal sections of the hive will accomplish nearly or quite as much as inverting; and after the first inversion has caused the bees to completely fill the frames, but little if any inverting will be needed.

After the frames are completely filled with comb, the peculiar construction of the hive enables us to manipulate hives instead of frames; and perhaps my readers will not be surprised when I say that I value this feature more than I do its invertibility it is the grand function of the hive.

I worked 50 colonies the past season for comb honey. One-fourth of them were in the "new hive," and most of the swarms were hived in it. I secured 100 lbs. of surplus, per colony, from *clover alone*. I am aware that it is the *bees* that gather the honey. I know we have been told repeatedly that a colony of bees will store as much honey in a nail-keg as in any hive; but in all seriousness, I should like to ask, is this assertion *true?* When coming home from the convention at Indianapolis I stopped off and made Mr. Heddon a short visit; and among the many things we talked over was this one of the influence that the hive may be made to exert upon the energy of the workers. I did not remember it, but Mr. Heddon thought he had, within the last three years, written upon this topic under the heading of

PRESENT CONDITION.

If Mr. Heddon did write upon the subject, I think but little attention was paid to it; at least, I knew that, when he mentioned it, it struck me as a new idea. I consider it well worthy of consideration, and will do my best to illustrate it.

We have all noticed with what energy a newly hived swarm works; the "present condition" is different from what it was in the old hive. Let a full case of finished or nearly finished sections be removed from a hive, and an empty case be put in its place, and the bees are sometimes quite slow in making a start in the empty case; if, instead of removing the case of nearly finished sections, it is raised up and an empty one placed between it and the hive, the "present condition" is such that the bees work with renewed energy to fill the newly added case, and thus connect the upper one with their brood-nest. Mr. Heddon told me, that, what first called his attention to this subject, was that, when breeding for qualities in bees, he found there were two different causes for good work. One (the one he wanted to breed from) was a fixed characteristic of the variety; and the other was an energy resulting from proper "present conditions." With an extremely tall hive, top-storing would not be a success; neither would side-storing be profitable with a very shallow hive, because the "present conditions" would not be favorable to success in either case. Mr. Shuck says, in his circular, that his attention was first directed to invertible hives by accident. A colony of bees, although strong in numbers, refused to enter the honey-boxes. The honey-board holding the boxes was removed, when it was found that the combs were built diagonally, and the hive was inverted for the purpose of putting the combs into proper shape. Just then he was called away for the day; the honey-board with the boxes was hastily placed on the bottoms of the hive (temporarily, as he thought), and the cover put on the boxes. On inspecting the hives at night the boxes were found to be full of bees; honey-making went on apace, and the strength of the colony increased, so that they stored 85 lbs. of honey after the first set of boxes were taken off. This well illustrates what a change of "present condition" can do. Re-arranging or interchanging the parts of a hive often starts *new determinations* in the bees. Under the head of "present condition" it would be proper to consider the right amount of brood and honey in proper shape, and this is much governed by the depth, size, length, and width of the hive. The kind of communications between the cases would also come under this head.

In my opinion, this question is a very important one, and well worthy of consideration. In a short article like this I can do little more than touch upon it; but I trust I have said enough to set my brother bee-keepers to considering whether the style of hive used may not be made to have a bearing upon the amount of honey stored by the bees.

Rogersville, Mich. **W. Z. Hutchinson.**

I agree with you, friend H., in regard to what you are pleased to term "present condition." I have seen a new swarm cluster on the outside of the hive, and refuse to go near it for several days, in the very height of the honey season. Sometimes I have driven them in and up into the boxes by means of a smoker; and when they once got started to work they would gather enormous quantities of honey in a very short time. Now, it is not new swarms only, but, a good many times, powerful colonies, that work very little, or do only about half what they might do, if they felt like it. If there is any thing we can do in the arrangement of hives to start up this latent energy, by all means let us do it. I am very glad indeed that you begin to think that reversing is not really necessary after the combs are once filled out clear to the bottom-bars. It will save a great deal of complication and machinery in making hives and frames. Now, then, how many others have found out that alternating answers nearly or quite as well as inverting?

BEE-LEGISLATION.

THE SUBJECT FROM ANOTHER POINT OF VIEW.

I DO not doubt that most bee-keepers are willing to believe, with Dr. Miller, that some kind of legislation directed toward the protection of the interests of bee-keeping would be a good thing. Class legislation is usually a good thing for those in whose favor such legislation is done. But if the professional bee-keeper is to be protected by law against the amateur, why not protect the creameries against the farmers who make butter in a small way, sometimes much to the detriment of prices? If we apply this principle of special legislation to any one business, let us apply it to all. When one man is "first in the field," and has built up a thriving grocery trade, let us keep all other grocers at a respectful distance. The first comer has invested thousands of dollars, perhaps, in buildings, stock, and "fixtures," and other grocers in his vicinity might render these totally worthless on his hands. The same is true of almost any line of business. The mass of humanity will not stand aside to let the favored few carry on the business of the world. Few men would be willing to accept the theory that government has the right to forbid a citizen following whatever honest occupation he may choose. To me it is a self-evident truth, that every man should have an equal chance with his neighbor in the struggle for existence.

I have kept bees for three years in the town of Denison. The locality is far better than the open country, for the streets and commons are covered with white clover, and nearly every lot is white with fruit-blossoms until late in the spring. I was first in the field, but I do not think myself any more entitled to these privileges than Mr. S., who last spring brought three times as many colonies into town as I have, and located them less than two blocks away. I believe he has as much moral right in the territory as I have; and I further believe that any law that would exclude him from keeping bees in the town, or that would convey to me the right of territory, would be both wrong and unconstitutional.

Next spring my bees will be sent to my farm, four miles from town. What justice would there be in a law that gave me control, not only of my own farm, but also of that of Mr. Brown, my nearest neighbor? If he keeps a few colonies only, they will not interfere with my business; and if he keeps many colonies they will be unprofitable to him unless he joins with me in the cultivation of crops that will furnish flowers for the bees. I certainly should resent any law that would sell to him any rights whatever in regard to my farm.

I believe the good doctor is joking about this whole matter of bee-legislation. He has baited his hook for "suckers," and caught one at the first cast, much to his edification, no doubt. If he is really in earnest, and proposes by such laws to keep out the small producers who regularly knock the bottom out of the local markets every year, I should be slow to fall in with his project, for these "small producers" are, many of them, the boys on the farms. They take this means of earning a few dollars in the fall when a little money is so much longed for by the average farmer-boy. I have been there, and know just how it is with the boys. Every year the papers are full of advice in regard to keeping the boys on the farm. Let us help keep them there by making bee-keepers of them. But whether they be boys, girls, men, or women, who swamp the markets with small lots of honey, let us do our best toward teaching them to obtain their honey in marketable shape, and prices will be safe. The dealers, too, are much to blame for this frequent demoralization of the local markets. They do not guage prices according to quality, as they do when buying butter and other farm produce; but if section honey is selling at 20 cts., they pay farmers 15 cts. for it in pails, whether the quality be good, bad, or indifferent. In such a market, clean new comb honey in pails ought to be worth at least 18 cts.; black and soiled comb, anywhere along the scale to zero.

Not long since, my grocer, who knows nothing about bees, lifted from a jar on his counter a piece of comb that had evidently been the home of half a dozen generations of baby-bees, with the remark that he rather liked comb honey that was "somewhat discolored." With a dull knife I cut crosswise of the cells and showed him the cocoons of the young bees. He was utterly astonished to learn what the silky material was, and now he not only refuses to eat such honey but also to buy it. Let us take the local dealers in hand. Z. T. HAWK.

Denison, Iowa, Nov. 22, 1886.

Friend H., after the article from friend Miller had gone to print, some thoughts occurred to me in the line of what you have been saying. The real solution of the matter seems, after all, to be in educating the boys and girls, the small farmers, the grocerymen, and everybody else, up to the standard of modern bee culture; and even then there is much further to be done. When some neighborhood gets to be overstocked with bee-keepers and bees (just as it is in your own case), we want the Christian spirit that actuated father Abraham when he said to Lot, "If thou wilt take the left hand, then I will go to the right; or if thou depart to the right hand, then I will go to the left." It won't pay for bee-keepers to crowd together in one spot; and, indeed, it is far from being necessary, for in almost every township and county there are large tracts where there are not bees enough kept to gather a tenth part of the honey that goes to waste every year.

FRIEND FRADENBURG'S CHEAP COMB HONEY.

HOW HE MANAGES TO SELL IT.

I WAS never successful in getting nice section honey in my locality, so I got an extractor and thought I would raise all extracted honey; but I have found it a drag to dispose of it. The people nearly all seem to want their honey in the comb; but, as Mrs. Chaddock has it in GLEANINGS, page 887, they don't want to buy boards. I have for some time thought of telling how I have found a plan to sell them the comb honey, and without the boards; but reading her article just now made me jump for my writing-material, and so here it goes.

First, to get the comb honey that will be nice and white, that can be sold cheap, fill an upper story of a hive with nice new brood-frames; exclude the queen from them, but let the workers fill them full, and they are pretty.

HOW TO SELL THEM.

I make a case that will hold ten or twelve brood-frames, with one side glass, but have the case about 4 inches deeper than the frames. Next I have a tin tray made that will just fit in this case, and slide down to the bottom, 3½ inches high, with a fly-tight lid, and handles on each end on the outside, to lift it with when it is done. Next I laid a layer of comb-honey that I cut out of unfinished sections in the tin tray, and poured extracted honey over them to merely cover them; then I hung in the brood-frames of comb honey to fill the case, put in a case-knife and a galvanized-iron spoon, and took the case over and set it on the store counter, with the glass side in front. In a very short time, word was sent over that they wanted more. The first case was made two years ago, and the cry has only been "more, more," and never a word of complaint. This season I fixed up two such cases, and put in about 100 lbs. in each, and set them in a buggy, and drove over all the stones I didn't miss, 12 miles, to Uhrichsville, to test its shipping possibilities, and not a cell was broken. Of course, I fastened the combs so they could not shake or flop around much. The merchants there are equally well pleased with the arrangement. Do you get the idea? The merchant can lift out a frame, cut out the amount a customer may want, be it an ounce, a pound, or five or ten pounds, and set the frame right back, and all the drip goes in the tin tray, and does not need to daub the counter or other goods a bit; and, further, if the weight does not come out even, a spoonful or two from the tray below will make it. A. A. Fradenburg.

Port Washington, O., Nov. 22, 1886.

Friend F., this reminds me that almost the first comb honey I ever raised was by picking out nice L. frames of white sealed honey while we were going over the hives. They were hung upstairs with a dripping-pan under them to catch the drip; and when we wanted a plate of honey for company, we just cut it out. Sometimes the friends would go up into our honey-room and see our stock, and it was almost sure to give them the bee-keeping fever to take a look at it. I feel sure that more comb honey could be secured in this way than in any other kind of a honey-box. You do not tell how much the merchant received from it, nor how much it netted you. Nowadays it makes a great deal of difference about how *much* a product sells for.

HEADS OF GRAIN
FROM DIFFERENT FIELDS.

BAGGING GRAPES.

In a recent number of Gleanings, the practice of bagging grapes is advised, in order to protect the cluster from birds and insects. This is good advice, as it is about the only method known by which perfect clusters may be secured, in sections where the grape-rot is prevalent. The bags are not proof against chickens, or, at least, only partially so; but they do serve admirably to prevent rot, and to keep off troublesome insects. Any one who has never tried the plan will be surprised and delighted when he sees the perfect and beautiful clusters that may be raised with so little outlay of time and money. It is not necessary, however, to use bags or sacks. All that is required is, that the clusters be covered. For this purpose it is just as well to use a bottomless sack, or, to make the matter more simple, take a sheet of some kind of paper that will endure storms; wrap around the cluster; fasten at the top with a pin, and the job is done. The paper may be left open at the bottom, but it is doubtless better to gather it in the hand, and give it a twist; but a pin is not required. It may require a little practice to do the work quickly and efficiently, but it is not hard to learn how.

There is one thing that must not be neglected, and that is, to do the work in time—almost as soon as the grapes form. A few days' delay will often render the work ineffectual, so far as preventing rot is concerned. Most people prefer grapes thus grown, to those ripened in the open air. The difference between them consists, for the most part, in the texture of the skin. The skin of bagged grapes is rather more tender than that of those grown in the open air. This is no disadvantage, except when grapes are to be marketed. Tender-skinned sorts like the Concord can not be grown for market very successfully by this plan, unless the market is quite near, in which case the grapes will often sell for two or three cents more a pound than open-air grapes. The difference is often so great that the bagged grapes are the only ones that are marketable at any price.

Will it pay? Most assuredly it will pay to grow the home supply in this way, except in localities where good grapes can be grown without the use of bags (that is, if it pays to grow grapes for home use. It appears that some people think that it pays to grow only such things as can be converted into cash; but that it is a luxury not to be thought of, to eat grapes if they can be sold, and a waste of time to raise them to grow them for home use alone). As to the profit in bagging grapes for market purposes, it all depends upon the cost of the work, and the price at which the grapes can be sold. Some who have tried it say that it pays, others that it does not. W. J. Green.

Ag. Exp. Station, Columbus, O.

BROOD IN THE UPPER STORY; QUEEN-EXCLUDING HONEY-BOARDS.

May I ask you a few questions? 1. In making a two-story hive for extracting, 10 L. frames below, 10 above, would you construct it so you could use a queen-excluding honey-board between?

2. In running 100 colonies for extracted honey, in how many would you expect to find brood in the upper story, providing you left the lower story intact, and no queen-excluding slatted honey-board between?

3. At the bottom of many brood-frames there is a space of ½ inch, more or less, not filled in with comb; and by putting on an upper story the bees will generally build down the comb solid to the bottom in the upper story, without the queen-excluding slatted honey-board; now, would they do the same if the queen-excluding slatted honey-board is used?

4. Not using the queen-excluding slatted honey-board, which do you consider the best bee-space—⅜ or 5-16 between upper and lower frames?

Fair Haven, Vt., Nov. 4, 1886. E. L. Westcott.

In the first place, friend W., I would just about as soon the queen would go in the upper story as not, when we are working hives for extracted honey. You can, however, easily prevent it by using a perforated zinc honey-board. As the slatted ones are thicker than those made of perforated zinc, you would have to increase the depth of your upper story in order to use them; whereas the Simplicity hives are all right for the plain zinc honey-boards. In running 100 colonies for extracted honey, very likely you would find brood in every one of them without the use of perforated honey-boards; but, as I said before, this is no objection to me. I think the bees would build the combs down to the bottom of the bars of every frame in the upper story, just the same as if the perforated zinc were used. I consider ¼ in., or 5-16 in., the best bee-space; ⅜ inch would be more likely to result in small combs.

A NOTE FROM AUSTRALIA.

Friend Root:—I certainly must address you by this name, as I look on you as a very good friend to all bee-keepers, and to me in particular. If it had not been for getting your A B C book I should have been groping in darkness for years. The majority of bee-books published don't go into details, and the unfortunate novice gets in a complete fog; and, in fact, he would be better off without them. I am getting some Italian queens from Chas. Bianconcini. I have received a letter from him, and his price is nearly double what he charges to America, and then he doesn't guarantee safe arrival. I am sorry to say that our prospect for a good honey-crop, in this district, is not very promising; but down on the coast they are having a good season. F. A. HUDSON.

Bathurst, New S. Wales, Oct. 6, 1886.

Friend H., I feel pretty certain that our friend Bianconcini will not charge you more than he does us, if you buy as largely as we do, and other circumstances are equal. We consider him to be a very fair, honorable man.—By all means, say "friend Root" when you are writing, if you feel like saying so.

BITTER HONEY.

We have had a very poor season this year, and the bees, as a general thing, have not made enough to keep them through the winter. I have had to feed mine. We have not had so poor a season for years; but very few have taken any surplus honey, and those that have are complaining. Will you explain to me what makes the honey so bitter? All that I have seen is so strong that it will make you "squeal." W. H. DICKINSON.

Deep River, Conn., Nov. 4, 1886.

I can not tell you, friend D., what makes your honey bitter. A good deal has been written in regard to it in our back volumes, and several plants have been mentioned as the probable source. Perhaps some of our readers can throw some light on the subject. Just before going to press with this form we notice the following on page 745 of the *American Bee Journal*, from the pen of Dr. J. P. H. Brown, Augusta, Ga.

> Some kinds of plants impart their odor and flavor more lastingly to the honey than others. After honey granulates and is again reduced to a liquid condition, the original odor and flavor are to some extent lost.
>
> That some few plants impart to the honey, besides the flavor, their medicinal and toxical properties is a fact, although denied by a few apiarists whose observation extends only to the familiarity with honey gathered from a few plants, such as white clover and basswood, and probably a few others. Illustrations: *Helenium tenuifolium* (I have heard it called dog-fennel by some persons, but it belongs to a different order of plants. Dog-fennel is another thing), is a weed, supposed to be an exotic, that is found in places in the South along roadsides. It commences to bloom about the first of August, and keeps on until frost. The leaves have a bitter, nauseating taste, and the extract, in the shape of tea, was used to some extent during the war as a substitute for quinine in the treatment of chills and fever. The old fields in my neighborhood are covered with it, and in some seasons considerable of this honey is gathered. It is as bitter as the plant, and possesses all the medicinal properties. Of course, I can not sell it, but it does for breeding-purposes.

OLD-FOGY FARMERS.

Our market here is a fair market, brought about by putting honey up in good style and of good quality. We are bothered here as in other places (as I see mentioned in GLEANINGS) with old-fogy farmers bringing in their honey in any kind of shape, just ruining our market. Our honey ought to be put up in the best possible shape, and of the best quality—at any rate, have the best sell first, and then we have the best all the time. There seems to be a little "free gratis" on our part. We fix up our honey, and get no more than those old farmers. I think the remedy is to organize and get together, if we can, and let them see their error. This is our conclusion, if the bees live till spring to help us out. It is our intention to winter our bees potato-hole fashion; and the way winter is setting in with 4 inches of snow on the ground, it's time the little imported fellows were stored away.

Clarksburg, Mo., Nov. 13, 1886. C. H. MCFADDIN.

THE INFERIORITY OF THE PURE BLACK BEES.

My queen I purchased of you has raised 8 queens. They all now have fine swarms. The smallest has 17 lbs. of honey; hive and all, without cover, weighs 42 lbs. I had one swarm of hybrid bees that made 112 lbs. of comb honey in 1-lb. sections. One other swarm made 100 lbs. I got 14 cts. per lb. for all. I have 19 swarms to go into winter with, all in fair shape. My neighbors have some bees, but there isn't one swarm in five that has honey enough to winter on. They are blacks mostly. I live 25 miles from St. Joseph, on one of the loveliest prairies that the sun ever shone on. It abounds with white clover. The weather is fine; the bees are having a nice fly to-day, Nov. 14, 1886. JOHN BLODGET.

Empire, Mo.

LEGISLATION TO PREVENT ENCROACHMENT OF OTHER BEE-KEEPERS OCCUPYING THE SAME FIELD NOT NECESSARY.

Bees are in fine condition for winter, after a very favorable summer. The majority of farmers in this neighborhood are beginning to keep bees, and are making a success of it by using the chaff hive, which is no doubt the best hive now in use, both for summer and winter. What does Dr. C. C. Miller mean? Would he prevent, by law, farmers from keeping bees on their own land? Why should there be a monopoly of bee-keeping, any more than of any thing else? A. F. STAUFFER.

Sterling, Ill., Oct. 30, 1886.

REPORTS DISCOURAGING.

UNFAVORABLE REPORT FROM TEXAS AGAIN.

IN this particular locality the bee-business has been any thing but encouraging the past season. The prospects were favorable in February, but have been growing worse all the while.

Early in the season foul brood made its appearance, and so far I have heard there is no one who has not suffered more or less loss. One of our leading bee-keepers has lost a great many colonies, but thinks by the persistent use of phenol he has nearly wiped it out. There has been but little surplus honey, and that from honey-dew. I think the experience of the past season would have cured the worst case of bee-fever. T. F. MCCAMANT.

San Antonio, Texas, Oct. 18, 1886.

BEES DON'T PAY.

I have just been reading GLEANINGS for Nov. 1; and although quantities of unread papers and magazines are at hand—having been too busy with my bees and honey to keep "read up"—I did not stop reading GLEANINGS when I once began, until I read all it contained, from cover to cover. I think I must subscribe for it next year, although I am almost decided to go out of the uncertain and toilsome business of bee-keeping, as it doesn't pay these times. There are so many bees here that honey is too plentiful to bring a good price. I sell good strained honey (just as free from bits of comb as extracted) at 7 cts. per lb., while the best white comb is 10 cts. Bees have not done well; the honey-crop failed in July. D. C. AYARS.

Moawequa, Shelby Co., Ill., Nov. 4, 1886.

REPORTS ENCOURAGING.

OVER 100 LBS. OF HONEY PER COLONY.

I BEGAN in the spring with 6 colonies. I took 634 lbs. of honey—about 100 of it in the combs, the rest extracted. This is besides what was used in the family, and we used it every day. I had no increase.

ALSIKE.

I sowed alsike clover with the red for meadow. At cutting time the Italians were working strong on both kinds, while the blacks were working only on the alsike. They also worked on the second crop of both clovers. I think the hay was better by having the alsike with it. I think I shall sow both kinds together in the future. I have had the best success in getting a "good catch" by sowing the seed on a light layer of snow in the later part of March. B. D. SIDWELL.

Flushing, O.

36 COLONIES, AND 10,000 LBS. OF HONEY.

My cousin has 36 or 37 swarms, and he has secured this season 10,000 lbs. of honey.

Lancaster, N. Y. OLIVER D. SEITZ.

FROM 70 TO 110, AND 5000 LBS. OF HONEY.

I have over 5000 lbs. of white comb honey, a fair crop for 70 colonies, considering drought. I increased to 110. JOHN A. WILLIAMSON.

Lodge, Piatt Co., Ill.

60 BARRELS OF HONEY YET TO SELL.

It has been a busy time this season, taking care of the bees and then marketing honey. We have 60 barrels of honey yet to sell. I have had no time to write, but I think I can get time to have a little talk with the boys after awhile. E. FRANCE.

Platteville, Wis., Nov. 19, 1886.

TURKEY-HILL APIARY.

I started in with 10 colonies of bees; increased them to 20, and took half a barrel of honey this last June. I now have about 500 or 600 lbs. to extract, which I will do as soon as I get time. We have had an excellent honey year. S. BRAEUTIGAM.

Rentchler's Sta., Ill.

218 LBS. OF HONEY FROM ONE SWARM.

I commenced the season with 35 colonies, increased to 80, and got 3000 lbs. of honey—2785 comb, and 215 of extracted. I have the Holy Lands and Italians. The former are the best honey-gatherers I have. From one young swarm, June 8, I secured 218 lbs. in 1-lb. sections. J. B. CRAVEN, 35—80.

Dixon, O., Nov. 10, 1886.

FROM 3 TO 21, AND 300 LBS. OF HONEY.

I commenced with three colonies in the spring. I increased them to 21 good strong hives, with plenty of stores for winter. I obtained 125 lbs. of comb honey, and 175 lbs. of extracted. I use foundation in 2-inch strips for starters in lower story, the same as in the sections. R. R. RYAN.

Bradshaw, Neb., Nov. 8, 1886.

A BEE-KEEPER 75 YEARS OLD.

I have been keeping bees for about 20 years, and this is the first season they have made any surplus to amount to any thing. They have given me this year about 300 lbs. of extracted honey, and about 100 lbs. in sections. This is not much, but I hope it is the beginning of better success. I am nearly 75 years old, and I am still able to attend to my bees, and hope to be for many years yet. I have 30 stands, but the surplus I got was from about a dozen stands of hybrids. HENRY J. ALVIS.

Montrose, Lee Co., Iowa, Oct. 12, 1886.

"SOLD LOTS OF HONEY."

This has been a very poor year for honey, although the fall has been favorable. Buckwheat made a very good flow, and the alsike we sowed in the spring gave considerable honey, so that they kept up breeding until late, and generally have enough honey to winter on. Honey is selling from 15 to 20 cts., and we are making quite a home market. We secured quite a large space at our granger fair, and made a nice exhibit, and sold lots of honey, and created quite an interest in bees and honey. GEO. W. WILLIAMS.

Economy, Ind., Oct. 29, 1886.

THIS YEAR THE BEST OF ALL.

Seven years ago I began bee-keeping, and this year has been the best of all. I commenced the season with 12 stands of my own, and 24 stands on shares, all very weak. I did not expect any honey or swarms at all. The fall of 1885 was very dry, and I did not feed any, which put my bees in bad condition. I took over 1000 lbs. and 22 swarms. The net proceeds for this year is $71.00. I have now 23 stands of my own, packed up for winter in Simplicity hives. I ordered one from you some time ago. I made my own hives. I made an extractor, which works all right. The honey crop in this part of the State is good. I have tried the Doolittle plan of forming nuclei, and succeeded very well.

LEWIS GLOVER.

Darkesville, W. Va., Oct. 28, 1886.

THE SUCCESS OF AN A B C SCHOLAR.

The goods I ordered all came in good shape. I have finished extracting, and now can make my report. I am an A B C scholar 4 years of age.

Number of colonies last spring	16
Increased to	82
Sold	1
Prepared for winter	81
Honey sold this season, pounds	1941
Honey now on hand	1419
Amount used on our table, estimated at.	240
Total	3600
Wax, pounds	30

Our bees are all in good shape, with plenty of good honey to winter on.

Of the honey, about 1600 lbs. is comb, and the rest extracted. The bees are as near pure Italian as I can keep them, and they gather honey nearly every day when it is warm enough. We have lost quite a number of swarms (I clip queens now), because we have not given our bees the attention they should have had this season. Our honey will average us about 10c. per pound. I have made all my hives, frames, sections, etc., so far, with hand-saws, planes, slitting-gauges, and miter-box; but I hope to buy sections and a Barnes saw for next year. JOEL C. MERRIMAN.

Wheatland, Mich., Nov. 15, 1886.

NOTES AND QUERIES.

POND'S METHOD OF WINTERING, SUCCESSFUL.

LAST winter I adopted Mr. Pond's method for wintering, and was so successful that hereafter I always wish to follow that method, as nearly as I can. You know he wants plenty of young bees with which to go into winter quarters. MRS. J. A. KEITH.

Brockton, Mass.

TOOK THE BEST PREMIUM.

I want to tell you that my comb honey took first premium at our county fair last week. The friends asked if it was not *imported* honey.

Macon, Miss. MRS. ELOISE FERGUSON.

THE SOOTY APPEARANCE OF HONEY.

The busy season is just over, and I can read bee-journals more carefully. I have seen just that sooty or smoky appearance this season in honey, and feel fairly satisfied it is caused by a slight mixture of honey-dew, not causing a bad flavor at all.

R. F. HOLTERMANN.

Brantford, Canada, Oct. 27, 1886.

"THE BEE-KILLERS."

The A B C book I received two years ago, has proven an invaluable aid to me. I use the Simplicity hive, a cheap make. My experience tells me to buy the best manufactured hereafter. Bees have done poorly this season. The bee-killers (box-hive men) got nothing this season. I got enough for home consumption. I winter in the cellar, without any loss. D. R. PHILLIPPS.

Fulton, Mo., Nov. 1, 1886.

HUNTING BEES.

The fall of 1884, I found 22 colonies in the woods; and in the fall of 1885, 31. Some of them I followed 2 miles in the woods. We have large woods here in Van Wert and Paulding Counties, O., and Allen Co., Ind. Every man who wishes to have good stock in his apiary will have to keep the black bees hunted out of the woods. There is nothing I like better than to have nice bright bees.

Dixon, O., Nov. 10, 1886. J. B. CRAVIN.

SWIMMING A RIVER IN NOVEMBER, WITHOUT ANY BAD RESULTS, AND NO CATNIP TEA, EITHER HOT OR COLD.

I discontinued the use of drugs, or doctoring, as it is called, some years ago. I had to swim the Big Manistique, at Burns' Crossing, last week, and no catnip tea or fire-water tonic. But when I reached the other side I felt as light as when just out of the army, and could run easier than I walked, *before* the icy river was crossed. F. M. BENHAM.

Petoskey, Mich.

THE WAX-PLANT.

[The following clipping has been recently sent in to us in regard to this vegetable wax. Can any of our correspondents give us any further light upon the matter?]

The wax-plant is now grown on a large scale in Algeria, and its product is gradually finding its way into the markets of the world. The process of separating the wax is simple. The fruit, inclosed in a bag of coarse cloth, is plunged into boiling water, on whose surface the substance soon floats. The wax is of the same chemical composition as beeswax, and is likely to be largely used in place of it. It is stated that these wax-plants may be seen growing wild in Pennsylvania and the Carolinas.

TOBACCO COLUMN.

MR. JOB H. MORGAN, of Worthington, handed me your GLEANINGS, and also gave me two colonies of Italian bees. I see in GLEANINGS that you will send a smoker free to any one who uses tobacco, and will quit the same. In good faith, I promise to abstain from the use of tobacco; and if I use it any more I will send you the price charged for smoker.

JAMES B. FOWLER.

Lumbersport, W. Va., Nov. 8, 1886.

I prevailed upon a relative of mine, Mr. F. G. Cook, of Murray, Ia., to quit the use of tobacco. Will you please send him a smoker? If he ever commences to use the weed again I will pay you for it. H. A. COOK.

Spring Hill, Kan., Nov. 5, 1886.

I have this day received from you a smoker, in consideration of which I hereby promise to quit the use of tobacco in every form. If I ever resume the use of the weed I pledge myself to pay for the smoker. D. H. HURST.

North Lawrence, O., Nov. 8, 1886.

S. Y. Kirk has quit chewing tobacco, having used it for 13 years. If you will send him a smoker I will see that you get your pay if he ever uses it again. R. H. KIRK.

Roanoke, Denton Co., Tex., Oct. 23, 1886.

A friend of mine, seeing your promise to give a smoker to any one who would give up the use of tobaco, has quit it. His name is George Joslyn. Please send him a smoker. If he ever uses it again he will pay for it. BYRON GUEST.

Maple Landing, Monona Co., Ia., Nov. 5, 1886.

Robert Reed works for me, and this is what he says: "I am going to quit using tobacco, and sign the pledge for a smoker. If I ever use tobacco again I will pay Mr. Root one dollar." If you want him to have the smoker, send to above address.

J. O. HARLAN.

Jolietville, Hamilton Co., Ind., Nov. 10, 1886.

I am a new subscriber to GLEANINGS, and a beginner in bee culture. After seeing in your Tobacco Column that you would send a smoker to any one who would stop the use of tobacco I quit the habit. If I break the pledge I will pay you $1.00 for the smoker. I like your A B C very much. It is the finest book published, on bees. W. H. STACY.

Mifflin, Iowa Co., Wis., Nov. 8, 1886.

WILL PAY FIVE TIMES THE PRICE OF THE SMOKER, IF HE RESUMES THE USE OF TOBACCO.

Noticing in GLEANINGS your offer to those who would quit the use of tobacco, and seeing the number who have already responded, forces me to the conclusion that you have struck the right way to accomplish a great object. In our childhood days, it was much easier to get us to do a certain thing when gentle means and a little *pay* were the inducement, than if force and harsh means were resorted to. After having been a slave to tobacco for thirty-odd years—smoking and chewing—you can add my name to your list of reformers, and send a smoker; and if I ever use tobacco again, in any form, I will pay you five times the price of the smoker.

J. F. HARNER.

Taylorville, Christian Co., Ill , Nov. 8, 1886.

OUR OWN APIARY.

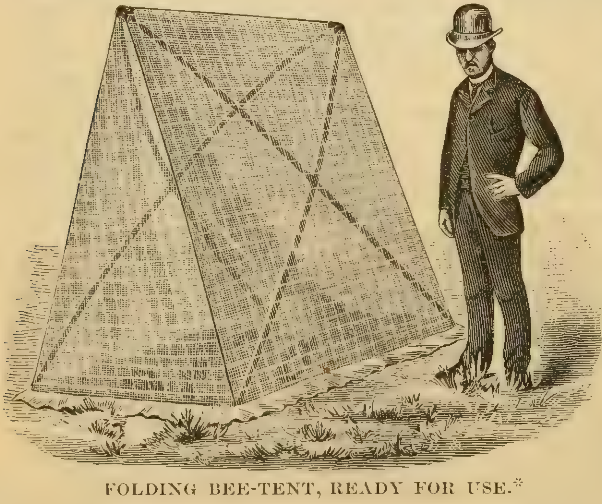
CONDUCTED BY ERNEST R. ROOT.

CONVENIENCES FOR THE APIARY.

NOW that the active work in the apiary has ceased, I propose beginning with this to write a series of three or four articles upon what I shall call "conveniences for the apiary." As the term signifies, I do not necessarily mean that the tools or implements I shall recommend are indispensable to a well-regulated apiary, but, rather, are helps, or, more correctly, conveniences, such as I have found from my experience of nearly ten summers in our own apiary. Although I had more or less to do with bees long before that time, my real active experience does not date back over ten years ago. I may touch upon a few old things, but I hope to present them in a new light. With this brief introductory I will first take up

THE FOLDING BEE-TENT, AND ITS USES.

I believe I have once or twice referred to the bee-tent during the past year. From these short occasional references, doubtless many of our readers would be pleased to know more of the various uses to which this tent may be applied to advantage. As we have just had some new engravings made of it, I will first present to you the bee-tent ready for use — the figure at the right indicating the height of the tent.

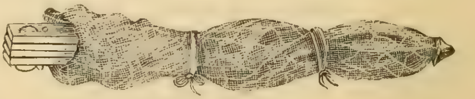


FOLDING BEE-TENT, READY FOR USE.*

If the fellow didn't look so *awful* conceited, I would own up that it is your humble servant; as it is, I will say that it is the apiarist.

You will observe that the tent is about six feet from the ground to the peak. The ground space is 4x6 feet. Thus you will see that there is ample room for a hive as large as the chaff hive, with plenty of room for the operator to work besides. The entire woodwork in its construction is simply four strips of basswood, 8 feet long, and tapering from the bottom to the top. They are crossed in such a way, and bound with strong cords, as to make a gable with convex sides. The whole is then covered with a sort of sack made of mosquito-bar. The result is, that the entire weight of the whole structure is only 6 lbs. (How to make these tents, see A B C of Bee Culture, under head of ROBBING.)

When it may be desirable to store it away, it may be quickly folded into a bundle, as represented below.



TENT FOLDED.

The tent, as thus folded, we shove into a couple of loops four feet apart, made by U-shaped cords, attached to screw-eyes in the ceiling of the work-shop adjoining the apiary. The tents, as they hang suspended in our work-shop, are just above our heads, and yet within easy reach of the hands, for immediate use as occasion may require. In regard to its use we will first consider

ITS UTILITY IN STOPPING ROBBING.

As I have already told you, on page 658, 1885, how it can be used to *stop* robbing after robbing has got fairly under way, I will not go into details here. It is sufficient to say, that when a colony is discovered as being robbed, quickly place the tent over the hive, and anchor the former down. If there is not already a hole or slit in the peak of the tent, one should be made. The robbers, on coming out of the hive, will bump about in the cage for a few minutes, and finally make their escape through the hole in the peak; but not one will return the way he came out. In a couple of hours all will be quiet; but, as the old adage runs, prevention is better than cure. I value it chiefly as

A PREVENTIVE OF ROBBING,

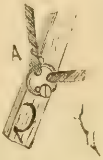
which I will now proceed to describe more at length. We will suppose that the honey-flow has suddenly stopped, and in going over the hives we discover that robbers are just beginning to show their annoying presence. They follow us about, and just as soon as the hive-cover and enameled cloth are removed they commence their pillaging. If we proceed thus all day, toward the latter part of it we shall find quite a little swarm of robbers making repeated raids into the hives. We are then obliged to contract the entrances of all nuclei; and if we continue to work thus, the next day we will unhesitatingly affirm that the bees are "unusually cross."

Now, it would be very desirable to avoid all this; hence we will take our "stitch in time." We proceed to the workshop, draw out the tent from its two loops, which I described, and set it on end outside.

---

*Our artist has shown the bottom fringe of the tent as common cloth; it is nothing but a continuation of mosquito bar.

We spread apart the basswood strips until each pair form sa letter X. We next grasp one of the rings on one corner of the tent, and draw it over the screw-head situated at the base of the strip, as seen in adjoining cut. In like manner we adjust the other three rings. The tent is now set up, and each of the strips will be bent in the form of a bow, as seen in either of the large cuts.



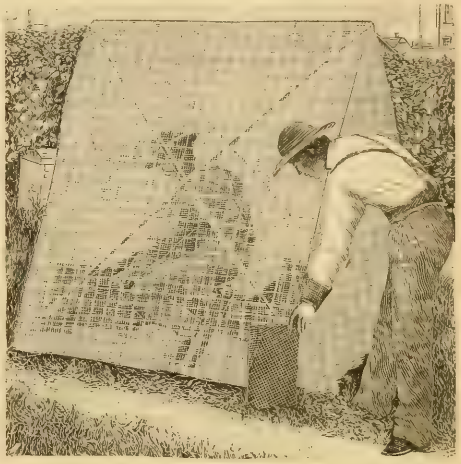
Having lighted our smoker, we grasp it with the right hand—the nearest corner of the bellows between the thumb and fingers. We now lift up one end of the tent and step inside. We grasp the two intersections of the cross-piece, at the same time holding the bellows of the smoker between the thumb and fingers. If you try a few times in different ways you will soon learn the knack of holding one side of the tent and the smoker at once, with ease. We can now cage ourselves and the hive together; take all the time we want to examine the hive, robbers or no robbers. The latter will buzz around the outside; but if we continue to examine the hive thus in rotation all day they will give it up as a bad job. If, on the other hand, the robbers have got started, they will be likely to follow the cage about for two or three days, even though they do not get inside. But if we are careful not to give them a "sip" of stolen sweets, they will finally let us alone.

Where there are no grapevine twigs to stick out and hinder, the tent will cause but little more trouble than the non-use of it, and if we take into consideration the fact that the use of the tent prevents the annoying presence of robbers, the time and trouble saved will vastly more than compensate any possible inconvenience it may occasion.

Right here I will say, before I forget it, if you use the tent awhile until the robbers have ceased buzzing about, then lay it aside for an hour or so, you will get the robbers started again, and then when you resume the use of the tent you are right where you started. If you wait too long before you resort to the tent, the robbers may be out in such strong force as to make even the tent fail of its object; for when the work with the hive is finished, and the tent is lifted off, the swarm of robbers will pounce into the entrance in such force as to make a real case of robbery; and before the inmates of the hive are aware of what is going on they have an "elephant on their hands." It is true, you may contract the entrance, but the bees will boil around every crack of the hive like mad hornets. When there are many queen-rearing nuclei in the apiary it doesn't pay to let things go so. It is and has been a standing rule in our apiary, that as soon as the bees show a disposition to rob, either quit work or use the tent—the latter alternative being the one most frequently adopted.

THE TENT INVALUABLE FOR TRANSFERRING.

The A B C of Bee Culture says, that the best time to transfer is during fruit-bloom. But it often happens that we want to transfer at some other time of the year. In all probability we shall need something to keep away the robbers. In order to give you a better idea of how to transfer by the use of the tent, we have had our special artist give you a picture of transferring in our apiary in process.



TRANSFERRING WITH THE TENT.

The operator inside has the old hive from which he is transferring, together with the new hive and all necessary fixtures for holding the combs in the frames. Besides these he has a saw, chisel, uncapping-knife, smoker, bee-brush, a large shallow drip-pan to catch drippings of honey, and clean wired frames. To make his work as easy as possible, he sits on a tool-box. In case he wants a frame or tool which by oversight he does not happen to have, an assistant, who may be engaged elsewhere in the apiary, at a call brings him whatever he desires. In the engraving you observe the assistant is in the act of passing an empty comb under the mosquito-netting.

You may think that transferring in this tent is in pretty close quarters, but I have transferred in this way a number of times easily and suceessfully, and the tent proved no real hindrance. However, I always removed one of the sides of the box hive outside of the tent, and then arranged my work in as small a compass as possible, to allow the tent to cover all.

THE TENT FOR GETTING BEES OUT OF SECTIONS.

Dr. Miller, in his "Year Among the Bees," suggests the possibility of using the bee-tent for this purpose, although at the time he wrote I believe he said he had not tried it. This fall, in my conversation with him, he stated he had used the tent the past summer for getting bees out of sections, and that it worked admirably. Although we have not tried this experiment exactly here at the Home of the Honey-Bees, yet from my knowledge of the workings of the tent in similar experiments I am sure it would work. The *modus operandi* then would be something like this: Get as many bees out of the crates of sections, when taking off honey, as may be possible, either by shaking or smoking. Next, quickly carry crate or crates of honey, with adhering bees, and place them under a bee-tent. In like manner place others under the tent until there are as many stacked together as can be covered by the tent. Leave for a time or until the bees have all crawled out and clustered in the peak of the tent. There, through the hole which I have described, the bees will escape, and return to their respective hives; and if the tent has been securely anchored down in the mean time, no robbers can gain access to the crates. These, after being freed from bees, are now ready to take to the honey-house, when the sections can be removed and cleaned in readiness for market.

THE TENT TO CATCH SWARMS.

Something over a year ago, D. A. Jones, in the *C. B. J.*, related the following incident: While he was at one of his out-apiaries, a swarm came out; when it had got fairly into the air, another began to come out. The thought struck him to immediately clap the tent over the hive from which the bees were pouring. This his man did; and when they had disposed of the other swarm they returned to find the other caged in the peak of the tent.

GLEANINGS IN BEE CULTURE.

EDITOR AND PUBLISHER.
MEDINA, O.

TERMS: $1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, DEC. 1, 1886.

Blessed is the man whose strength is in thee.—PSALM 84: 5.

OUR subscription list is running up with a sure and steady pace. We now have, up to date, 6074. Many thanks, friends.

MICHIGAN STATE BEE-KEEPERS' ASSOCIATION.

WHILE dictating these editorials I am waiting for the train to take me to Ypsilanti. I expect to have many good things to tell you on my return.

ORDERING EARLY.

REMEMBER our discount for this month is 5 per per cent—a drop of 3 per cent from last month. If you desire to get the lowest prices in supplies order early. With our new machinery and increased facilities we think we can give you better goods than ever before.

IS FOUL BROOD CURED IN OUR APIARY?

A NUMBER of our friends have written us something like this: "I am very glad to hear that you have at last cured foul brood." We have not yet claimed that. We did say, that, as brood-rearing had ceased, foul brood had of necessity stopped. If it shall not re-appear in the spring, *then* we shall think we have cured it.

OUR PREMIUM LIST.

YOU will notice, inclosed in the back of this issue, our supplement and premium list. Although we have in former years offered awards to those of our patrons who have solicited names, we have felt that this year they ought to have a larger and better collection from which to choose. Most of the presents therein presented are new goods, and are well suited for holiday gifts. If you can not secure *new* names, hustle in the old ones before their subscription expires, and get something. We would ask you to preserve this Premium List for future reference.

BRICKS OF CANDY.

Have you nice sealed combs of stores laid away which to give all the colonies this winter that may be running short, before spring? If you haven't, now would be a good time to make and have in readiness some bricks of candy. (How to make, see A B C of Bee Culture.) These bricks you can lay right over the cluster of any colonies, such as you may find, during a few of the warm sunny days of winter, to be in need of stores; you can usually determine, with a little practice, whether such colonies are running short, by lifting up one end of the burlap and "hefting" the ends of all the frames.

THE CHRISTIAN'S SECRET OF A HAPPY LIFE.

WE are pleased to notice that we have just received another shipment of this great book, amounting to 1250 copies; and although it is considerably enlarged, having several new chapters, the price is reduced to 25 cents bound in paper, and 50 cents in cloth, gilt edge. If wanted by mail, add 5 cents extra for postage on the paper bound, and 8 cents on the cloth. When I first read the book, some four or five years ago, it seemed to me it must prove such a great help to those struggling toward godliness that it ought to have a very large circulation among the people; but I hardly dared hope we should be able to sell it at the rate it has been called for.

QUEENS AS PREMIUMS.

ONE of our correspondents wishes to know what we can offer in the way of queens as premiums. For the benefit of those who may prefer queens to any other presents we will make the following offer: For 10 new subscribers we will send, the first of next May, one of our best imported queens; for 6 new names, a select tested queen; for 4 new names, an untested. Remember, at this offer the queens are to be sent in May. If you desire to have the queen sent at any other month, write us. The names can be secured now, and sent in; but you must state, at the time of sending, that in return you desire to draw a queen or queens, according to the terms of this offer. We will then book your order for next May.

THE NEW BEE-KEEPER'S MEDLEY.

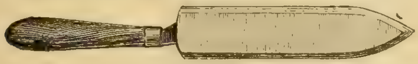
THE above, which we mentioned Nov. 1st, is now framed and hangs over our desk. As we sit reading letters from our bee-friends from all over our land, it gives us peculiar pleasure, after reading their productions, to view their faces. We come to know our friends and their peculiarities from their writings; and to look upon their faces makes us feel face to face with old friends. In some cases we are surprised, and we mentally exclaim, "Why! I didn't know he looked like that." Again, our opinion is confirmed—"Just about such a looking man as I thought." This face indicates that he is good-natured, intelligent, or, perhaps conceited. Although some of the faces appear not quite natural, yet in general the medley as a whole will help us to recognize most, if not all of the faces, if we should see them at a convention.

GETTING RID OF LIFE-INSURANCE AGENTS.

One of our subscribers, a life-insurance agent, seeing the little note on page 915, under the above caption, writes: "Tell Ernest, that if I should get after him he couldn't scare me as he did the other fellow. I'm not afraid of bees." Very true; but then, you are away over in New York. Still, if you should ever think best to come to Medina, and talk with me in regard to the merits of the "semi-tontine," let me know just a little before hand, and I will contrive to have some Carroll Cyps in readiness for the occasion. I will also manage to have all the veils and smokers missing, except my own—a liberal offer, don't you think? The other fellow (the one who weighs 200 lbs.) has since been around, but he very cautiously asked, "Got any bees about you?"

ABBOTT'S NEW HONEY-KNIFE.

Our friend C. N. Abbott, ex-editor of the *British Bee Journal*, has brought out a honey-knife made of Sheffield steel; and even after paying duties and imports we are enabled to furnish it at the regular price of the Novice honey-knife. The cut of it below explains it by saying that the blade is 2 inches wide and 8½ inches long.



ABBOTT'S UNCAPPING-KNIFE.

Of course, this knife can not take the place of the well-known Novice honey-knife, and other similar knives, for its office is for uncapping and *nothing else*. If wanted by mail, add 10 cents extra for postage and packing.

DECLINE IN THE PRICE OF HONEY-JARS.

We are pleased to receive the following letter from friend Muth:

> We have made a change in the price of our honey-jars, of which please make due notice in your next number of Gleanings. Hereafter our price for square glass flint honey-jars will be:
>
> | | |
> |---|---|
> | Dime jars (a gross in a box), with corks, per gr. | $3.00 |
> | ½-lb. " " " " | 4 00 |
> | 1-lb. " (a gr. or ½ gr. in a box) without corks, per gr. | 5.00 |
> | 2-lb. " " " " | 6.50 |
> | Corks for 1 and 2 lb. jars, " | .75 |
>
> In lots of 5 gr. jars or more, assorted if you choose, we allow a discount of 5 per cent.
>
> Flint glass jars being the nicest jars for honey, and prices having been reduced, we have concluded to abandon the trade in green-glass honey-jars. Chas. F. Muth & Son.
>
> Cincinnati, Ohio, Nov. 22, 1886.
>
> P. S.—I inclose our jobbing price list of honey, and will add that our trade in jar goods is better than ever. Size and shape have been uniform for years, and is known to the trade and consumers, and no suspicion rests on its purity. There is no eastern extracted honey in any shape in Cincinnati, although their jars were more stylish (or fancy) than ours, and 5 or 10 years ago they seemed to be strong competitors. M. & S.

The above prices will be the same that we charge here.

SHALL WE ALLOW OUR HIVES TO BE COVERED WITH SNOW?

I for one say, let the snow come—the more the better, and under no circumstances attempt to meddle with it at all. I have never yet known a hive of bees to be injured by snow—not even where sleet and freezing rain closed the entrances entirely, and I don't know that I ever heard of a case where I was satisfied that the snow or ice did any harm. If a bee-hive could be made as tight as a glass jar, and the only opening were closed up with ice, it might do harm; but no bee-hives that I know of are made in that way. Disturbing the bees by brushing the snow away, or tramping it down, *does* do harm, for we have had several cases of the kind reported in our back volumes; that is, the hives where the snow was brushed away, or tramped down about the entrances, did not winter as well as where they were let alone.

CAN BEES BE DECLARED BY LAW A NUISANCE?

It seems our Canadian friends are also about to have trouble over this question. A blacksmith named McIntosh was annoyed by the bees owned by a neighbor named Harrison. McIntosh claimed that the bees flew all over the neighborhood, stinging the people. They annoyed the horses in his shop, and made trouble when the women-folks were making preserves. The jury brought in a verdict that the bees were a nuisance, and that he was entitled to an injunction. The judge, however, refused to grant an injunction, but reserved it for argument in a full court. And now our Canadian friends are talking about a Canadian bee-keepers' union. A bee-keeper residing quite a distance away says he for one will give five dollars, to see the case fairly tried. The editors of the *C. B. J.* propose to do as well; and as the case has been presented to me, I for one feel like offering my five dollars also. Of course, we do not wish to gain our case by the money we raise, but we do wish to have the case fairly and squarely presented, before any decision is made. Keeping poultry is oftentimes as annoying, if not more so, than keeping bees, but what court would say a man could not keep chickens?

CONVENTION NOTICES.

Nebraska bee-keepers will meet for their next annual session in Lincoln, Neb., on the second Wednesday in Jan., 1887.
H. N. Patterson, Sec.

The Keystone Bee-Keepers' Association will meet at Court-House, at Scranton, Pa., on Tuesday, Dec 14, 1886, at 10 A. M.
Clark's Green, Pa. Arthur A. Davis, Sec.

The Vermont Bee-Keepers' Association will hold its annual meeting in Burlington, Vt., on the 13th of Jan., 1887. The Programme is not fully made up, but it is expected there will be a two-days' session. R. H. Holmes, Sec.

KIND WORDS FROM OUR CUSTOMERS.

A KIND WORD FOR THE A B C FROM ONE OF OUR AUSTRALIAN FRIENDS.

Please send to me by post, 2 copies of A B C, cloth; the ones I have had are all sold, and also the one to arrive next mail. It's the best on bees published. I would not be without a copy on any account. Fred'k A. Hudson.
New South Wales, Australia.

The A B C book sold on sight — no need to talk up its merits. I just handed it to a friend who had called, and as soon as he opened it he said, "I must have you get me one." C. A. Lower.
Wabash, Ind.

GLEANINGS AND HOW IT PAYS TO ADVERTISE IN IT.

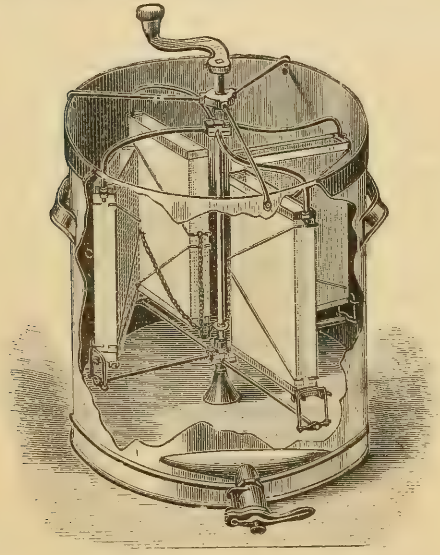
Gleanings is not the only paper in which I have advertised, but it certainly has done the best of any for me, as its readers seem to put more confidence in those short advertisements, even though the advertisers be strangers. I will here say, that if any one has sent me money for which they think I have not rendered full value I will with pleasure make it satisfactory. D. S. Hall.
South Cabot, Vt.

Dadant's Foundation Factory, Wholesale and Retail. See advertisement in another column. 3btfd

BEE-HIVES, ONE-PIECE SECTIONS, SECTION-CASES, FRAMES, &c.,

Of superior workmanship, from SMITH & GOODELL, Manufacturers of and Dealers in Apiarian Supplies, Rock Falls, Whiteside Co., Ill. Send for Price List.

STANLEY'S Automatic Honey-Extractor.



Great Improvements and Enlarged Facilities for Manufacturing.

Reduction in Price of 4-Frame Machines.

Parties wishing to handle the Automatic Extractor and dollar Smoker should write for terms to agents, and inclose 50 cts. for cut of the extractor to insert in their catalogue.

10.000 Circulars out for 1887.

Send for circular, with testimonials from those using the machines and smokers.

I MEAN BUSINESS.

Address **C. W. STANLEY,**
23d **Wyoming, N. Y.**

IN order that I may pay off my debts, and devote my whole time to preaching the gospel, I offer my entire apiaries, consisting of about 90 colonies of Italian and hybrid bees, 60 empty hives, 3 extractors, and other bee-supplies, for sale at a great sacrifice. Persons wishing to buy would do well to correspond with me *immediately. I must sell.* JAS. ERWIN.
21tfd Smith's Grove, Warren Co., Ky.

DADANT'S FOUNDATION FACTORY, WHOLESALE and RETAIL. See advertisement in another column. 3tfbd

SAY! the **ACME PAPER-HOLDER** holds all sorts of small things, as papers, letters, almanacs, magazines, pamphlets, cards, etc., and does it quick, before they get lost, stolen, blown away, or the baby gets them. By mail, **10**c.; two, **15**c.; five, **25**c.; twelve, **50**c. Agents wanted.
Address **N. E. JOHNSON, Medina, O.**

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ad's intended for this department must not exceed 5 lines, and you must SAY you want your ad. in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. Of course, this department is intended only for bona-fide exchanges.

WANTED.—To exchange for cash, or good horses and mules, 200 colonies of bees in Simplicity frames; also 40 acres of land adjoining the city.
20tfdb ANTHONY OPP, Helena, Phillips Co., Ark.

THOROUGHBRED fowls, Brown Leghorns, S. S. Hamburgs, W. C. B. Polish, P. Rocks and Wyandottes, Bonney's, Forbes', Hawkins', Wilcox & Fultz' strains. We will sell for cash, or exchange for fdn. and beeswax. Price list free.
18-19tfd A. H. DUFF, Creighton, Ohio.

I HAVE about 5 lbs. of spider-plant seed. I will exchange the same for different kinds of flower-seed or plants of any sort that are useful and ornamental. J. W. ROSS,
23-24-1-2d Phair, Brazoria Co., Texas.

WANTED.—To exchange for extracted honey, cash, or offers, one Adams horse-power, cost $40.00; never has been used over half a day. I will take $20.00 for it. It is just as good as when it came from the factory. 22-23d C. M. DIXON, Parrish, Ill.

WANTED.—To exchange for pure extracted honey, apiarian supplies, or offers, one Star bicycle, but little used. Write for description.
Address C. H. WATSON, Newtown, Bucks Co., Pa.
22-23-24d

15 VARIETIES raspberries; fine plants, new varieties, in exchange for comb or extracted honey. For particulars, address E. T. FLANAGAN, Box 995, Belleville, Ill.—Eight acres in small fruits.
22-23-24d

WANTED.—Extracted honey for pure Pekin ducks, cockerels from Corbin P. Rocks, L. Brahmas, and Wyandottes; one black and six hybrid queens; also plants in the spring—Cuthbert raspberry, Cumberland Triumph, Mt. Vernon, and Sharpless strawberry. Please state price of honey, and what is wanted. G. A. FARRAND,
22-23 Kamm's, Cuy'a Co., O.

$3000 cash down will buy my store and contents, dwelling-house and stable, large lot with the same. A running stream, with carp-pond on lot; also 19 colonies of bees in Simplicity chaff hives. Will exchange for good land.
23d S. HEATH, Rimer, Armstrong Co., Pa.

WANTED.—To exchange merchandise or cash for new or second-hand chaff hives, Simplicity upper stories, drone and queen traps, wide and brood frames and separators. Write for particulars.
23d THOMAS DREW, So. Hanover, Mass.

WANTED.—A man to take charge of on shares, or buy, an apiary of 75 hives of bees in good condition. Address E. G. HEDDING, Paw Paw, W. Va.
23tfdb

WANTED.—An extra-fine large young bronze gobbler. Give strain, actual weight, and price.
23 C. L. DAVIDSON, Flemington, W. Va.

WANTED.—A foundation-mill, or offers, for a first-class incubator—been used three seasons.
23tfdb D. S. HALL, So. Cabot, Vt.

WANTED.—To exchange a fine pair of Toulouse geese or a swarm of bees for a pair of good pure-bred bronze turkeys.
23d O. G. JOSENHANS, Owosso, Shia. Co., Mich.

WANTED.—To exchange comb and extracted honey for Langstroth or Simplicity hives. They must be 8-frame, 1½-story, for comb honey, or any other hive that takes that size of frame.
23d Address LOUIS WERNER, Edwardsville, Ill.

OUR PREMIUM LIST.

HOW TO GET HOLIDAY PRESENTS.

IT is with some degree of pleasure that we inclose this, our supplement to GLEANINGS. As Christmas, with good old Santa Claus for the little folks, is drawing near, we hereby present to you our annual premium list of presents. Of course, our object in so doing is to increase the subscription list of GLEANINGS, and, as we hope, its usefulness. While some will prefer the cash commissions we have been offering for the collection of names, a very large number, especially the little folks, will prefer the presents; nor could they be induced to work for GLEANINGS under any other incentive. As we have just purchased a new lot of beautiful holiday presents, we would respectfully invite your careful perusal of the premiums herein presented. If you are of a literary turn of mind you will be interested in looking over our list of new popular books for old and young. Their beautiful bindings, embossed on side and back in gilt, will make them an ornament in any home. The younger members of the family will find pleasure in looking over our list of new toys. Then there is a collection of new tools, with a lot of other articles useful as well as ornamental. As apiarian supplies are so well advertised in our price list and elsewhere, we purposely withhold mention of them here as premiums. After looking over the list of presents herein described, should you feel that you have not the time to collect names, send us the cash for the article or articles you desire.

Now we should feel that there is one thing omitted were we not to give

A BRIEF TALK TO THE JUVENILES ON HOW TO OBTAIN PREMIUMS.

We appeal to you, little folks, because we believe that you can render us valiant service. Perhaps we can tell you how to go to work. At any rate we will suppose that your situation is something like the following:

There is Tom, way down in Arkansas, who wants a kite "awful bad." Then there is Frank, up in Wisconsin, who wants a magic lantern. The evenings are long, and he wishes to throw pictures on the wall, and charge 5 pins for admittance to his show. Mary doesn't care about boys' premiums, so she wants a doll. How shall you get the names? Why, old Uncle Phil, down the lane a piece, has kept bees in box hives "well nigh on to 40 year;" and then there is rich old farmer Jones, about half a mile out. He also keeps bees in box hives, and doesn't know much about "these 'ere new fixins'." Suppose you, my young friends (older ones too), take over to each a sample copy of GLEANINGS, and explain its merits, and the advantages of the improved methods over the old. It is easier said than done, I know; but you can try it. The urgent appeal of a young intelligent face will accomplish much. If you do not succeed, you can send in your papa's name, at any rate, before his subscription expires, and get something. There are box-hive men all over our country, and this is just the class of people whose names we want to put on our list. Will you help us, young and old?

PREMIUM RULES.

All collecting Premium names should read carefully the following rules:

1. You can close your list of names at any time, and call for the premiums due; or you can add to the list of names up to June, 1887. But—

2. Send along the names as fast as gathered (with the exact money), so that the subscribers may begin to receive the Journal at once.

☞Mark every name or list of names, *"For Premiums,"* if so intended, and we will credit them to the sender in our Premium Record.

3. *Be sure to give the Name, Postoffice, County, and State, of each subscriber and of yourself.*

4. **All sample copies** necessary to canvassers will be sent postpaid free.

5. Express or freight charges on the premiums can be best obtained at your own nearest express or freight office. When you order your premium, be sure to tell how to send, and give name, county, and State of your nearest express or freight office.

6. **To Foreign Readers.** Mailable articles, not exceeding 8 ounces, go to Canada for 10 cts. per parcel; but packages exceeding 8¾ oz. are excluded from the mails to Canada. To all foreign countries in the Postal Union, 18 cts. must accompany subscription for postage; and to all other foreign countries, 42 cts.

How to Send Money: Send money by P. O. order, registered letter, express money-order, on American Express Co., or get a N. Y. draft. For small sums of less than $1.00, we will accept clean postage-stamps, but we prefer postal-notes, but can not be responsible for the loss of either.

BOOKS! ✽ BOOKS! ✽ BOOKS!

BIG OFFER; A LIBRARY FREE.

For 2 New Subscribers to GLEANINGS, at $1.00 each, we will send any one of the following books. Postage 12c each extra if sent by mail. The price of these books to those who want to buy is 40c, or 52c postpaid. They are beautifully bound in cloth, with title in gilt, and contain from 200 to 600 pages, printed on excellent paper:

Arabian Nights Entertainment, 450 pages.

Children of the Abbey, by Roche; a very good and interesting story.

Dickens' Child's History of England; 341 pages. An authentic history of England; written by the very interesting author Charles Dickens—a book of real value to old and young.

Dickens' Shorter Stories, 350 pages of interesting and profitable reading-matter.

Half-Hours with Great Authors.

Half-Hours with Great Humorists.

Half-Hours with Great Novelists.

Half-Hours with Great Story-Tellers.

Gulliver's Travels and Baron Munchausen, by Swift and Rasp.

Ivanhoe, by Sir Walter Scott; 431 pages. One of the best writings of one of our best authors.

Lady of the Lake, with notes; Scott's best poem.

Jane Eyre; by Charlotte Bronte. A very interesting and thoroughly good story.

Last Days of Pompeii, by Bulwer. Now when that ancient city is being so thoroughly excavated, and reported in the papers, it will be interesting to read this old standard work in connection.

Last of the Mohicans, by Cooper; 358 pages—a most pathetic story of the struggles of a dying race.

Oliver Twist; Italy and American Notes, 519 pages, by Dickens, whose writings need no recommend.

Our Mutual Friend, Pickwick Papers, Martin Chuzzlewit, others of Dickens works.

Paul and Virginia, Rasselas, and Vicar of Wakefield, by St. Pierre, Johnson, and Goldsmith.

Bunyan's Holy War; 318 pages, by John Bunyan, the author of Pilgrim's Progress.

Pilgrim's Progress, by John Bunyan—a book that has a circulation second only to the Bible; 422 pages.

Robinson Crusoe; 472 pages—a book that every boy will delight in reading; by Daniel Defoe.

Romola, by Elliot.

Scottish Chiefs, by Porter.

Sketch Book, by Washington Irving; 374 pages—a collection of fascinating sketches by one of our best authors. Rip Van Winkle is one of the stories.

Life of Washington.

Life of Napoleon.

Swiss Family Robinson—a history of the privations and experiences of a family, from actual life.

Life, Speeches, and Memorials of Daniel Webster; a book of 552 pages, of surpassing interest to every boy who aspires to noble service of his country in an office of public trust.

Thaddeus of Warsaw, by Porter.

Cook's Voyages Around the World—a history of the thrilling adventures of that notable English explorer Capt. Cook.

The Christian's Secret of a Happy Life—new edition, enlarged; ought to be read by every Christian.

First Steps for Little Feet, by the author of the Story of the Bible.

Christmas Stories, by Dickens. If you do not believe in making Christmas a joyous time, you ought to read some of these stories.

Tom Brown's School Days at Rugby, by Hughes. An amusing narrative of a schoolboy's experience.

Life of Patrick Henry, by Wirt. A biography of one of the fathers of the Revolution.

For 1 New Subscriber to GLEANINGS, at $1.00, any of the following books will be sent, you paying postage.

Christian's Secret of a Happy Life. New edition, enlarged, paper cover. Price 25c; postage 5c extra.

Robinson Crusoe, in paper covers. Price 20c; postage 5c extra.

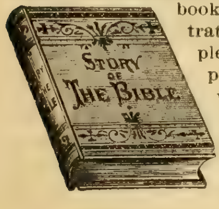
A Dose of Truth, paper cover. Just the thing for tobacco-users. Price 20c; postage, 3c extra.

A B C of Potato Culture, by T. B. Terry. Paper cover. Nobody should try to raise potatoes without reading this work. Price 35c; postage 3c extra.

A B C of Carp Culture, by Peirce. Paper cover. Invaluable to carp-growers. Price 35c; postage, 5c extra.

The Winter Care of Horses and Cattle, by T. B. Terry. Paper cover. An excellent talk by this most practical author. Price 40c; postage, 3c extra.

SOME MORE SPECIAL OFFERS ON BOOKS.



Story of the Bible. This is a large nice new book of 700 pages and 274 illustrations. It is so plainly and pleasantly written that grown people, as well as children, will hardly want to lay it down. In the hard passages in the Bible, difficult to understand, it makes a commentary that will be thankfully received by some others besides children. For 3 new subscriptions at $1.00 each, and 15c to pay postage, the above book will be sent free.

HOW
TO
KEEP
A
STORE
TERRY

How to Keep Store. A nice new book of 406 pages. If I mistake not, there are not a few among our readers who will be delighted to get such a book. It embodies the conclusions of Thirty Years' Experience in Merchandising. Eigth edition printed in 1884. Any one who sells goods at retail will find it a boon. This book will be sent free for four new subscriptions at $1.00 each and 10c extra to pay postage.

FABLES AND ALLEGORIES. The most beautiful piece of work in the way of a book that I have ever sold, and I do not know but it is the handsomest book I ever saw. It is a large-sized book of 512 pages, full of engravings of surpassing beauty. The paper and printing are probably equal to any thing in the way of a book now in the market. Our readers may ask, "What are the fables and allegories about?" Well, they are about you and me. As an illustration, in the center of the book you will find the fable of the lantern people which I gave on p. 345, May 15, 1885. I copied the story, but I did not have the wonderful pictures that the author has in this book. The book is written by the author of the Story of the Bible. There is but one fault to find with it; that is, it costs $2.00. However, if any of you want a book worth $2.00, every cent of it, you will find it in this book of fables and allegories. It will make you cry, if you don't look out; and the chances are very great that you will be better after you have cried. I never saw any thing in my life nicer for a Christmas present; or if you want a beautiful book to put on the center-table of your best room, you can not find a handsomer one for the money. Perhaps I am saying a good deal; but if you do not agree with me after you have seen the book, you can send it back and have your money returned. They are so large and heavy that the postage on them is 32c extra. We can sell two books for $1.75 each; three for $1.65 each; five or more, $1.60 each. The above book will be sent free to the person sending **6 new subscriptions** to GLEANINGS at $1.00 each, with 32c extra to pay postage, if sent by mail.

A YEAR AMONG THE BEES; by C. C. Miller. Price 70c; postage 5c, bound in cloth. Will be sent free for 3 new subscriptions at $1.00 each.

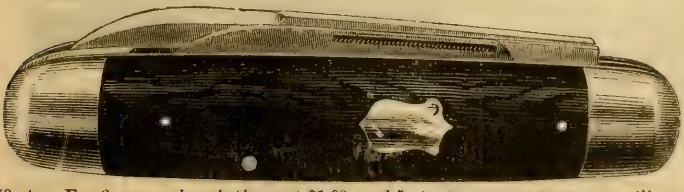
LANGSTROTH ON THE HIVE AND HONEY-BEE. That old standard work by the father of bee-keeping will be sent free for 6 new subscriptions at $1.00 each. Postage 10c extra, if sent by mail.

SUCCESS IN BEE CULTURE, by Jas. Heddon; will be sent postpaid for 2 new subscriptions.

Any other books in the book-list on cover page of Gleanings will be sent as premiums on the following basis.

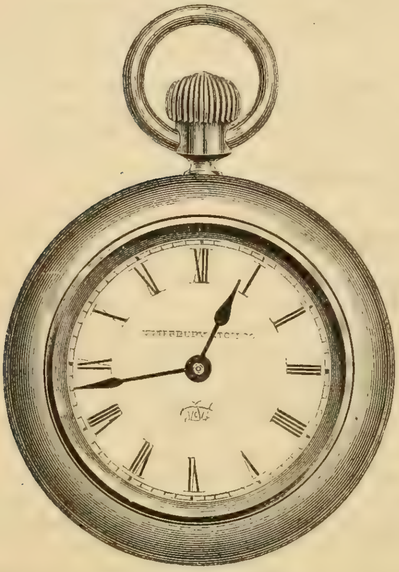
For *one* new subscription, books to amount of $	.20
" *two* " " " " " "	.45
" *three* " " " " " "	.70
" *four* " " " " " "	1.00
" *six* " " " " " "	1.75
" *ten* " " " " " "	3.00

MISCELLANEOUS ARTICLES.



Knife, Excelsior. Razor steel, hand-forged, brass-lined, one German-silver tip on the knife we send out, cut shows two. This is the very best knife we keep, and, in fact, is as good as any one would want. Price 50 cts. For 2 new subscriptions at $1.00, and 5 cts. to pay postage, we will send the above knife free.

"The Waterbury."



Waterbury Watch, Series E. Given for 5 new names at $1.00 each.

For a Christmas or New-Year's present, it is the prettiest and most useful article for a boy, man, or even for a lady, who teaches, or for any one who needs a timepiece (as they are rather small in size), of any thing that can well be imagined. The cases are nickel, and wear with a luster when carried in the pocket, surpassing even silver. The whole is put up in a very pretty box, with a book of instruction on the care of it; and every time I look at one, I can only wonder that they can be furnished for any such sum of money.

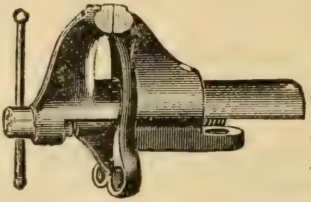
We will send the above, postpaid and registered, for $2.75, or the watch with GLEANINGS for 1 year, for $3.00. For 5 new subscriptions, at $1.00 each, we will send a watch free; or for $5.00 we will send GLEANINGS for 5 years to one address, and give you a watch free. Besides the above we have a few watches of the older styles which keep just as good time, and look almost the same. To dispose of these we offer them at the following rates:

Series C, postpaid, $2.50, or for 4 new subscriptions.

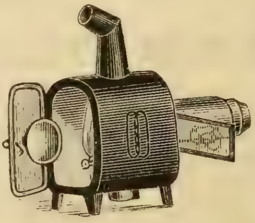
Series B, postpaid, $2.00, or for 3 new subscriptions and one renewal.

Series A, postpaid, $1.50, or for 2 new subscriptions and 2 renewals.

Remember, all these watches are carefully regulated and tested to run while being carried in the pocket. We also warrant them for 30 days. If the watch reaches you in bad order, or gets out of order inside of 30 days (neither of which is probable), send it back to us, being sure to put your name on the package. At the same time, write us, telling what is the matter if you can, and we will either send you another, or put the one you return in good order again, and send it back, you to pay postage. What boy has not often wished for the time to come when he could carry a watch that was all his own? Here there is a chance to get a watch free by **a very little effort.**



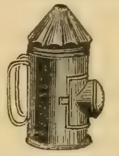
AMATEUR BENCH-VISE. This is a little beauty, and wonderfully handy for any one who likes to fix things up. The jaws are 1 inch wide, and the vise is 3 in. long. For **one** new subscription, with 6 cts. extra for postage, we will mail the above free. Price 15 cts.

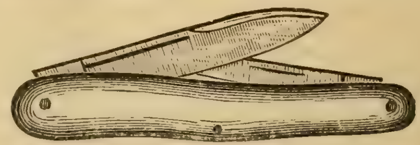


Magic Lantern. Price $1.00. This is the same kind of a lantern that sold for $3.00 a few years ago. It has a tin lamp, with glass chimney, a reflector, smoke-stack, and 2 lenses. It includes 12 slides, with 4 pictures on each, or 48 pictures in all. There is hardly any thing in the whole list that will please the little folks more than this. Directions accompany each lantern. For 4 new subscriptions at $1.00 each, we will send it free. It can not be sent safely by mail, and will therefore have to go by freight or express, with other goods.

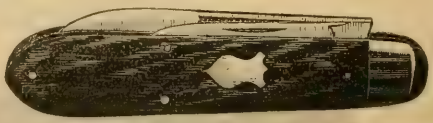
Music-Box. Price 50 cts. Postage 10 cts. extra. We have again succeeded in getting a music-box that plays one tune, which we can sell for 50 cents. They are a splendid little nstrument, and are usually sold for one dollar. For 3 new subsriptions at $1.00 each and 10c for postage we will mail one free.

Bull's-eye Dark Lantern. Price 25 cts. This is a genuine watchman's dark lantern, made of japanned tin, 4½ in. high, and 2½ in. in diameter; a bull's-eye glass, 2 in. across, and double handle on opposite side. Will throw a red, green, or white light. Will be sent free to the person sending **one** new subscriber at $1.00, with 10 cts. extra for postage and packing.

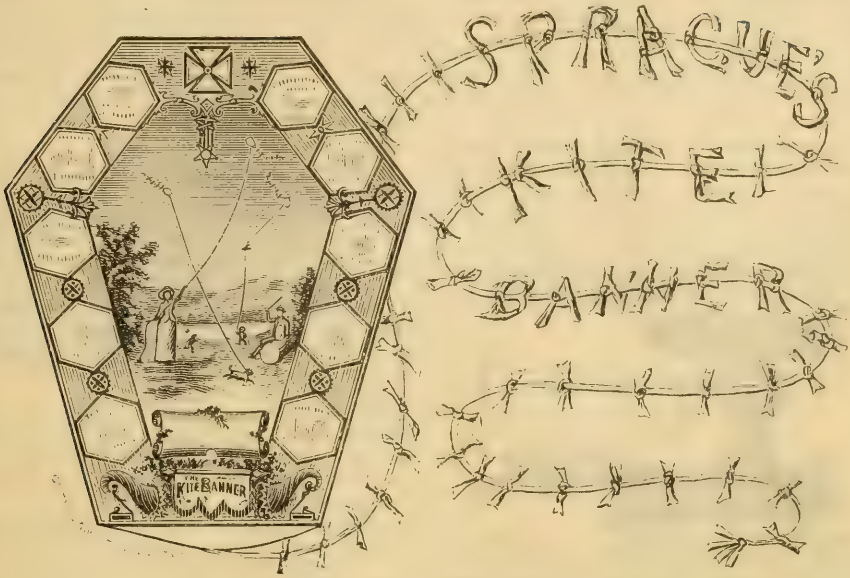




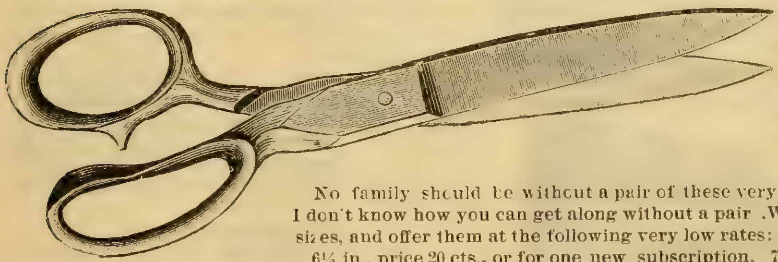
Knife, Two-Blade. This is a very good razor-steel knife, not quite as large as our 35-ct. knife. Price 25 cts. Will be sent for one new subscription at $1.00, and 4 cts. extra to pay postage.



Knife, Razor-Steel, 3½ in. long when closed. This is best hand-forged, and is so well liked that we have sold over 100 dozen of them. Price 35 cts., or we will send one free to the person sending us **one** new subscription at $1.00, and 5 cts. extra to pay postage and packing.



Kite, Complete. Price 10 cts. Postage 5 cts. Fun for the young folks. If you don't think it's fun to fly a kite, just try it. Read the artice in GLEANINGS for Nov. 1st, 1886. For one renewal, sent in *before* the time expires for which it is paid, and 5 cts. for postage, we will send a kite free; or we will send one postpaid for one new subscription at $1.00. Here is a rare chance for the boys to get a beautiful present free. Remember to send in your papa's name *early*.

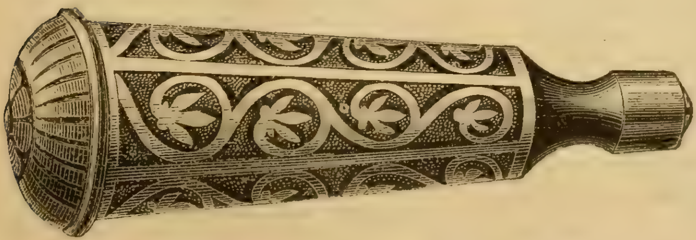


NICKEL-PLATED SHEARS

SOLID STEEL BLADES.

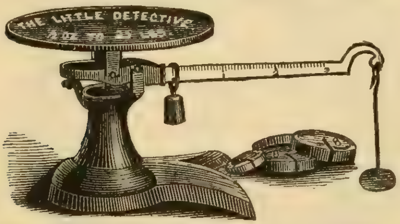
No family should be without a pair of these very fine goods. In fact' I don't know how you can get along without a pair .We have them of all sizes, and offer them at the following very low rates:

6½ in., price 20 cts., or for one new subscription. 7 inch, price 25 cents, or for one new subscription and one renewal. 8 inch, price 35 cts., or for 2 new subscriptions. 9 inch, price 50 cts., or for 2 new subscriptions and one renewal. 10 inch, price 75 cts., or for 3 new subscriptions. Postage extra, as follows: 4, 5, 6, 7, and 8 cents respectively. Bear in mind that these shears are not cheap in quality, but are hand forged, and of the best of steel nickeled over.



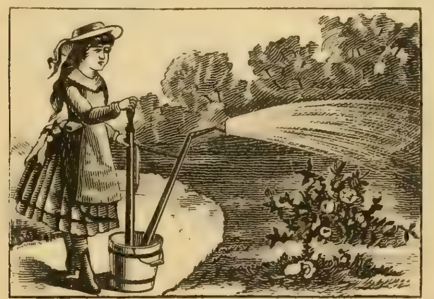
Tool-Handle, or Pocket Tool-Chest. An iron handle with 12 tools inside, which can be taken out, and any one adjusted to the handle. The tools are 6 assorted-sized brad-awls, 2 gimlets, 1 drill, 1 reamer, 1 scratch-awl, and 1 screw-driver. A very handy tool for many purposes. The adjoining cut is exact size. Price 35 cts.; postage 6 cts. extra. Will be sent for 2 new subscriptions at $1.00 each.

Carpet - Sweeper. Price $1.50. What housewife has not felt, at times, as she puts up her broom, with aching back and arms, "Oh for something to make sweeping a pleasure, and at the same time save my carpet from being brushed threadbare with a broom!" Well, a good carpet sweeper will do this; and after you have tried it you will not be without one. The sweeper we are now selling is called the "World," made by the Bissel Carpet-Sweeper Co. It has an arrangement for pouring out the dirt without stooping to open it. By placing the handle straight up and turning it on end, the door opens of its own accord; but it is held shut by the handle in any other position. We will send one for 6 new subscriptions at $1.00 each.



Little Detective Scales. A perfectly reliable scale weighing from ½ ounce to 25 lbs., making it invaluable for family use, and for weighing mail-matter. In fact, it is used largely by postmasters throughout the U. S. It has steel bearings and brass beam. Reduced price $2.00, or we will send it free for 7 new subscriptions at $1.00 each. With tin scoop, 50 cts. additional, or for 9 new subscriptions.

244-lb. Platform Scale. Price $3.50. A much larger scale, weighing from ½ oz. to 244 lbs. Has both platform and tin scoop. Has steel bearings and brass beam. Chatillon's make. We have sold nearly 200 of these the past season. We will send this scale free for 12 new subscriptions at $1.00 each. It weighs 45 lbs., boxed ready to ship.



Fountain Pump, or Sprinkler. Price $1.00. A very useful and serviceable article about any house. It will throw a stream of water ⅜ inch in diameter, to the height of 50 feet, and is very effective for putting out fires or arresting swarms. It has also a spray nozzle for watering plants, etc. It is just the thing for washing windows or whitewashing poultry-houses; 500 sold in less than a year. We will send one free to the person sending 3 new subscriptions at $1.00 each. If you want it by mail, send 60 cts. extra for postage and packing.

Parker's Fdn. Fastener. Price 25c. For fastening starters is sections. By far the most in use of any kind made. For one new subscription at $1.00, and 10c. for postage, we will mail one free.

For one old name, or renewal, sent in BEFORE the subscription expires.

Any article on the 5-cent counter of our price list that you may select, you paying postage if sent by mail. The following are a few Christmas goods, such as Santa Claus brings around for the young folks. Postage is indicated by the figure just before the name of the article.

4 | **Box of Water-Color Paints,** 24 different colors; a hair brush and mixing-saucer in a little wooden box; amusing and instructive to children.

3 | **A B C Cards,** 6½x10 inches; a stiff card, with capitals on one side and small letters on the other.

3 | **Box of A B C Blocks;** 6 wooden blocks, with the whole alphabet printed on them, and 3 pictures besides, in a neat box.

3 | **A B C of Animals,** 7½x10¼. This is a large 14-page book of colored pictures of animals and alphabetical rhymes and rebuses.

2 | **Linen A B C Books,** 10 pages, 4x5¾. Indestructible; full of pictures; just the thing for the little folks to learn their A B C's from.

4 | **Doll,** china head and limbs; will please the little girls.

2 | **Jumping Jack,** painted and striped like a circus clown.

1 | **Trumpet Balloon.** This is commonly seen at fairs, and sold for a dime.

2 | **Pocket Match-Box,** nickel-plated, and spring cover. The word "Matches" is stamped on the side.

3 | **Match-Safe, double.** Imitation of hammered brass, and a beauty for a nickel.

2 | **Sugar-shell,** brittannia; a beauty, and sold below cost at a nickel.

3 | **Butter-knife,** nickel-plated. This is another bargain; sold below cost.

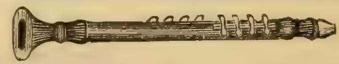
2 | **Toy Waterbury Watch;** a stem-winder; that is, by turning the stem the hands go round; chain included.

3 | **Humming Top.** This is a fancy colored tin top that hums a musical note when spinning.

REMARKS.—This will be a rare chance for the little folks to get Christmas presents. Get your papa, and your neighbor too, to give you the subscription price of GLEANINGS, and you can forward the names.

For one NEW name.

Any article you may select from the 10-cent counter, or two 5-cent articles, from our price list, you paying postage. The following are some more of Santa Claus' goods, with a few special bargains added.



3 | **Clarionet.** This is a wonder for a dime; has 8 keys, or a whole octave. You can play on it, "Home, Sweet Home," and many other melodies.

10 | **Tool-Chest.** A neat wooden box, containing a hammer, mallet, 6-inch rule, try-square, triangle, slate pencil, chalk crayon, paper-yard measure, etc.; a splendid present for a little boy.

6 | **Box of Water-Color Paints;** 15 colors, a bar of India ink, a piece of sepia, 2 crayons, blue and green, a brush, and 2 mixing-saucers, in a neat chromo wood box.

4 | **Juvenile Picture-Book,** 7½x10½; elegant colored picture story-books—Robinson Crusoe, Red Riding Hood, etc.

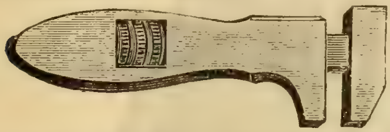
3 | **Linen A B C Book,** 14 pages, 6x7¾; larger than the 5-cent one. An indestructible juvenile primer.

6 | **Box of A B C Blocks**; 18 blocks, comprising the alphabet of colored letters, and 5 pictures; a never-ending source of amusement for a small boy.

4 | **Humming Top.** Same as the 5-cent one, but much larger.

4 | **Jumping Jack.** A much larger one than the 5-cent one.

2 | **Toy Watch.** One that ticks when you wind it; chain and charm included.



6 | **Pocket-Wrench,** adjustable. One of the best ten-cent tools in the list.

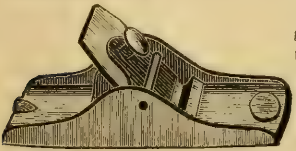
2 | **Purse.** Either **buck, kid,** or *imitation* **alligator.**

For one new name and one old one, or for three old names.

Any article you may select from the 15-cent counter, or three 5-cent articles, or one 5-cent and one ten-cent article, you paying postage. The following are a few special goods, some of which are not in the price list. Postage is indicated by the figure just before the name of the article.

| **Boys' Tool-Chest.** Same as the 10-cent one, but larger throughout.

3 | **Paper-weight.** Diamond-ground glass with a figure inside, an elephant, fly, horse, or turtle, with moving limbs, making them look for all the world like things of life.



6 | **Plane.** At first glance you might take it for a toy plane; but if you try it on a board you will find it is a plane in reality. They will sharpen a lead-pencil beautifully, trim up a woodcut or electrotype, take the corners off a rough box, reduce the width of a board, and do it all in a workmanlike and finished manner; and when they need sharpening, the bit is taken out or adjusted securely, by simply turning a single screw with the finger and thumb.

2 | **Purse, kid,** with nickel frame, ball clasps, and 2 pockets; an elegant purse.

4 | **Hand Mirror,** with bevel-edge glass, 2½x4.

4 | **Spy Glass,** or Toy Telescope, 1 draw. Will please any boy with an astronomical turn of mind.

For two new names or four old ones.

Any article on the 25-cent counter, or its equivalent on the lower counters. The following are some of the items on our counters, but not in the catalogue.

4 | **Purse,** either **buck** or **kid**; 3 pockets, lined; nickel-frame; an elegant present.

8 | **Knife-Box, Willow,** two compartments for knives and forks, and so strong that it will stand almost any amount of knocking around.

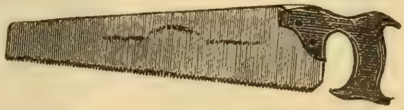
5 | **Hand-bag,** plaited straw, 8½ in. long, 3 in. wide, and 6 in. deep; very light and strong.

5 | **Wire Hair-Brush,** imitation rosewood back; a first-class article.

5 | **Lunch-Basket;** a combination of plaited straw and willow, with hinged cover and double handle; 4x7½ in. outside measure, and 4 inches deep; nothing nicer for a boy or girl to carry dinner to school in.

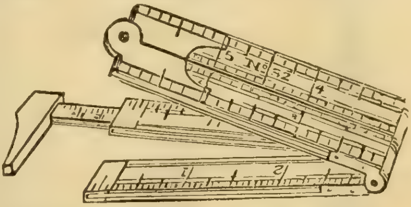
For 2 new names and one old one, or for 5 old names.

Any article on the 35-cent counter, or its equivalent on the lower counters, you paying postage as before. The following are some special goods.



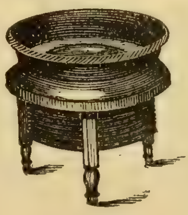
20 | **Carpenter's Hand-Saw,** 18-inch, cast steel. Who ever heard of a good steel saw, a foot and a half long, for such a small sum of money?

3 | **Rule, 1-foot Caliper,** brass-lind.



3 | **Rule, 2-foot, 4-fold,** brass-lined.

3 | **Rule, 2-foot, 6-fold;** can be put into the vest pocket if desired.



5 | **Magnifier,** 2 lenses on 3 brass feet.

3 | **Sugar-shell,** triple plated on nickel.

3 | **Butter-knife,** triple-plated on steel. Both the above are Rogers Brothers' best.

For 3 new names and one renewal, or for 6 renewals.

Any article from the 50-cent counter, or its equivalent from the lower counters, you paying postage if sent by mail.

| **Hand-Mirror,** plush back, and nickel folding handle; mirror is a 4×6 bevel-edge plate. This has been sold for $1.00, but we can sell it for 50 cents. Nothing nicer for a present.

6 | **Telescope.** Focal length, 30 inches; closed, 11½ inches; has 4 lenses, and magnifies about 10 diameters. This is a wonder for the money, and we will send it free for **2 new subscriptions.**

For four new names or eight renewals.

Any article from the 75-cent counter, or its equivalent from the lower counters, you paying postage, if sent by mail.

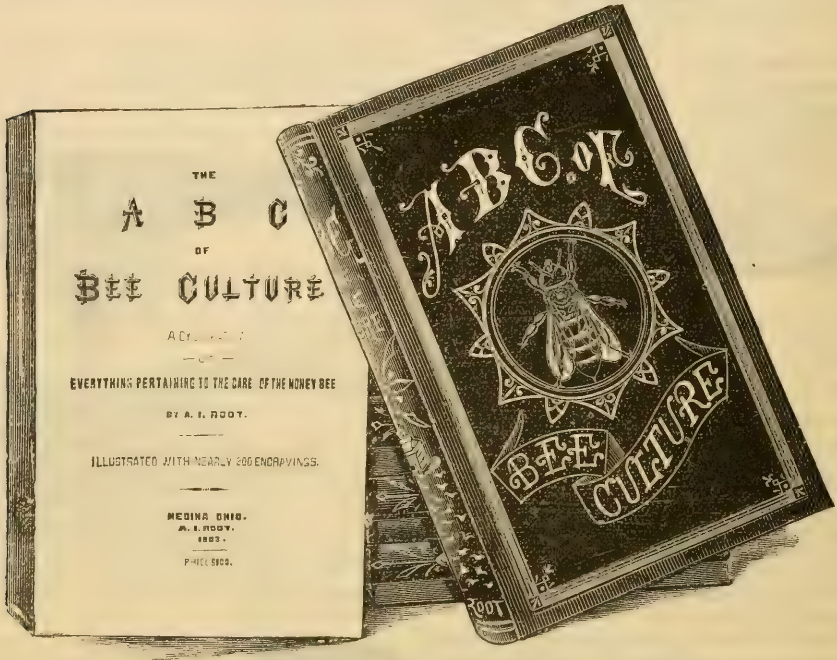
| **Nickel Clock, "Whistler."** This is an excellent time-keeper; and for one more new name you may have one with an alarm. Price $1.00 without alarm; $1.50 with alarm.

For five new names or 10 renewals.

Any article on the $1.00 counter, you paying postage if sent by mail.

OUR SPECIAL OFFER.

For 3 new subscriptions to GLEANINGS at $1.00 each, and 15 cents to pay postage, we will send a cloth-bound A B C of Bee Culture free.



THE
A B C
OF
BEE CULTURE
EVERYTHING PERTAINING TO THE CARE OF THE HONEY BEE
BY A. I. ROOT.
ILLUSTRATED WITH NEARLY 200 ENGRAVINGS.
MEDINA OHIO.
A. I. ROOT.
1883.
A B C OF BEE CULTURE
ROOT

AVERAGE SALE, NOW 400 PER MONTH.

THIS is a cyclopædia of 330 pages, and is beautifully illustrated with about 250 engravings, many of them full page. Some of the latter embrace a view of the apiaries and portraits of some of our largest and most successful bee-men. The whole work is elegantly bound in cloth, 7 inches wide, 10½ inches long, and embossed on side and back in gold. It would be an ornament on the center-table of any bee-keeper's home.

Especial care is used to explain in detail *how* Frames, Sections, Hives, Extractors, and other fixtures, are made and put together, the process being made clear by the use of many engravings. The comparative value of the different Races of Bees is fully discussed. Much is said of the many valuable honey-plants. Considerable space has been devoted to the subject of the Production, Shipping, and Sale, of Comb and Extracted Honey. The articles on Wintering contain the best that is known on that subject. Transferring, Queen-Rearing, Artificial Swarming, and other manipulations, are treated so that we hope our friends who are beginners may have no trouble in fully understanding how to operate.

The whole work is brimful of contagious enthusiasm, and the style so simple and instructive, that even the more advanced bee-keeper as well as the beginner may find pleasure and profit in its perusal. None of the matter is electrotyped, but all is kept in standing type, so when any new thing of importance comes up it can be inserted in its appropriate place. Its quick sales have warranted us in giving it frequent and thorough revisions. The present edition is greatly enlarged and improved, so that it is nearly twice the size of the one first issued, and no bee-keeper having an original copy can afford to be without this latest edition.

Since the first issue in 1877 its average sale has been over 200 copies per month, and the sale has been steadily increasing from the first. Prices: Neatly and strongly bound in cloth, by mail, $1.25; by express or freight with other goods, $1.10. In paper covers, by mail, $1.00; by express or freight, with other goods, 88 cents.

From the above prices there can be no deviation for any one; but each purchaser, after he has paid full retail price for one book, may order the cloth-bound to any of his friends on payment of $1.00, or the paper cover at 75 cents each. This discount we give to pay you for showing the book, explaining its worth, etc. To those who advertise A B C books in their price-lists and circulars, a discount of 40 per cent from retail prices will be made, and this discount will be made to all booksellers and newsdealers. To any one who purchases 100 at one time, a still further discount will be made, to be given on application, and the 100 may be made up of part cloth and part paper, if desired. Purchasers are requested not to sell single books at less than the regular prices, although they may sell two or more at any price they think proper; or the A B C may be clubbed with any other book or periodical, at such prices as the agent thinks proper.

HONEY COLUMN.

CITY MARKETS.

NEW YORK.—*Honey.*—In consequence of a large stock of comb honey on this market, prices will have to be reduced accordingly. We quote present prices as follows:

Fancy white, 1-lb. paper boxes or glassed	13
" " 1-lb. unglassed	12
" " 2-lb. glassed	10@11
Off grades 1@2c per lb. less.	
California comb	8@10
Fancy buckwheat, 1-lb. sections	8½@9
" " 2-lb. "	7½@8
Extracted, white clover, none on the market.	
" California 60-lb. tins	5@6
" buckwheat in kegs or bbls.	4@5
Beeswax	21@23

Fancy white in paper boxes and in glass are in better favor here than unglassed goods, hence the difference in price.

McCAUL & HILDRETH BROS.,
Dec. 7, 1836. 34 Hudson St., Cor. Duane St.

MILWAUKEE.—*Honey.*—The demand for honey is only fair, and values remain about the same yet. We continue to quote:

Choice white 1-lb. sections	12½@13
" " 2-lb. "	11@12½
" " in kegs and one-half bbls.	6½@7
Dark, bbls. and kegs	6@6½

Dec. 7, 1886. A. V. BISHOP,
142 W. Water St., Milwaukee, Wis.

CHICAGO. — *Honey.* — Market very quiet; sales (when any are made) are in a small way. Prices are nominal, and really without change, which is attributable to the lack of demand. Offerings of honey are distributed among many houses.

Beeswax, 22@25 cents.

Dec. 10, 1686. R. A. BURNETT,
161 So. Water st., Chicago, Ill.

ST. LOUIS.—*Honey.*—All kinds in abundant supply, and very low. The market seems to tend to lower rather than better prices, as the season advances. Choice white-clover, comb, 1-lb. sections, 12@13; extracted in cans 5@6c. Bbls. 4½@5; amber-colored honey and California white sage, in comb, sections, 10@11c. Broken comb, 7@9c. *Beeswax*, selected, 23@25; as it runs, 20@21.

W. B. WESTCOTT & CO.,
Dec. 11, 1886. 108 and 110 Market Street.

CLEVELAND.—*Honey.*—There is a slight improvement in the demand for honey, but no change in prices since our last quotations. The best white in 1-lb. sections sells at 13c, with an occasional sale at 14c; 2-lbs., white, 11@12. Dark, 1-lb., 10c. Extracted, slow at 6c. *Beeswax*, 25c.

Dec. 13, 1886. A. C. KENDEL,
115 Ontario St., Cleveland, O.

BOSTON.—*Honey.*—No change in prices; demand fair.

BLAKE & RIPLEY,
Dec. 11, 1886. 57 Chatham St., Boston, Mass.

DETROIT.—*Honey.*—The market continues to be overstocked; sales slow at last quotations; viz., 11@12½c for white comb honey.

Beeswax, 23c. M. H. HUNT,
Dec. 11, 1886. Bell Branch, Mich.

FOR SALE.—12 crates, of 48 lbs. each, all white-clover and basswood honey, which I will take $6.00 per crate for on board of cars here. Who wants it? Money sent with order. H. B. MORRISON,
Fayette, Iowa.

FOR SALE.—3000 lbs. comb honey, very fine; boxed ready to ship; want 14c, crates thrown in. Who will buy it? JOHN A. WILLIAMSON,
Lodge, Piatt Co., Ill.

FOR SALE.—2000 lbs. best clover honey in Root's "raised-cover pails." One set, 30½ lbs. $2.50; 4 sets, 122 lbs., $9.25. Boxed, they ship same as bbls.

Address OLIVER FOSTER,
Mt. Vernon, Iowa.

WANTED.—A quantity of extracted clover honey. Write lowest price, delivered here. H. BARBER,
Adrian, Mich.

WANTED.—A few hundred pounds of linn or clover first-quality extracted honey, put up in square cans, 2 to crate. How cheap can you sell it on board cars? S. S. LAWING,
Henderson, Webster Co., Mo.

FOR SALE.—1 bbl. of 550 lbs. net, and 5 kegs of 115 lbs. net each. All of which is No. 1 white-clover honey, well ripened. Will take 6½c per lb. for bbl. and 7c for kegs. Sample sent for 2-cent stamp.
R. J. BARBER, 818 E. Washington St.,
Bloomington, Ill.

4 H.-P. ENGINE FOR SALE.

A Bargain for the man who is in need of a First-Class Engine and Boiler.

This is one of B. W. Payne & Son's Eureka engines, the same that we advertise in our catalogue. It has run 3 months since it was new; has had a 10-foot galvanized-iron smoke-stack added, and is in perfect running order. The man who is holding it had to put in a larger one to meet the demands of his trade. The price of a new engine and boiler complete, no stack, is $275.00; but to make a quick sale we will sell this one with the stack for $225.00, free on board cars at Higginsville, Mo.

A. I. ROOT, Medina, Ohio.

DADANT'S FOUNDATION FACTORY, WHOLESALE and RETAIL. See advertisement in another column. 3tfbd

DADANT'S FOUNDATION

is asserted by hundreds of practical and disinterested bee-keepers to be the cleanest, brightest, quickest accepted by bees, least apt to sag, most regular in color, evenest, and neatest, of any that is made.

It is kept for sale by Messrs. A. H. Newman, Chicago, Ill.; C. F. Muth, Cincinnati, O.; Jas. Heddon, Dowagiac, Mich.; F. L. Dougherty, Indianapolis, Ind.; Chas. H. Green, Berlin, Wis.; Chas. Hertel, Jr., Freeburg, Ill.; Ezra Baer, Dixon, Lee Co., Ill.; E. S. Armstrong, Jerseyville, Illinois; Arthur Todd, 1910 Germantown Ave., Phil'a, Pa.; E. Kretchmer, Coburg, Iowa; Elbert F. Smith, Smyrna, N. Y.; D. A. Fuller, Cherry Valley, Ill.; Clark Johnson & Son, Covington, Kentucky; J. B. Mason & Sons, Mechanic Falls, Maine; C. A. Graves, Birmingham, O.; M. J. Dickason, Hiawatha, Kan.; J. W. Porter, Charlottesville, Albemarle Co., Va.; E. R. Newcomb, Pleasant Valley, Dutchess Co., N. Y.; J. A. Humason, Vienna, O.; G. L. Tinker, New Philadelphia, O., J. M. THE CANADIAN BEE JOURNAL.

WEEKLY, $1.00 PER YEAR.

JONES, McPHERSON & CO., Publishers, Beeton, Ontario, Canada.

The only bee journal printed in Canada, and containing much valuable and interesting matter each week from the pens of leading Canadian and United States bee-keepers. Sample copy sent free on receipt of address. Printed on nice toned paper, and in a nice shape for binding, making in one year a volume of 832 pages. 9tfb

GLEANINGS IN BEE CULTURE.

DEVOTED TO BEES, HONEY & HOME INTERESTS.

Vol. XIV. DEC. 15, 1886. No. 24.

TERMS: $1.00 PER ANNUM, IN ADVANCE; 2 Copies for $1.90; 3 for $2.75; 5 for $4.00; 10 or more, 75 cts. each. Single Number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent TO ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

DRONE COMB.

W. Z. Hutchinson Gives us Some very Valuable Points from Experience.

HOW TO HAVE IT BUILT IN THE BROOD-NEST, AND HOW NOT TO HAVE IT BUILT.

ON page 746 Cora Major gives a report of some very valuable experience in hiving swarms in empty brood-chambers. Four colonies built no drone comb; six built from three to six inches square of drone comb; two had one-half drone comb; three, one-fifth drone comb; while one had all drone comb and *lost their queen.* I wonder if the order of the last hive ought not to be reversed; that is, they lost their queen and *then* built all drone comb. I wish she could have told us the ages of the queens, as this is an important point. My only trouble with drone comb has been when the queens were old; and in such instances it is *possible* that the use of drone fdn. in the sections *might* remedy the difficulty. Almost all who have tried hiving swarms upon empty frames have been pleased with the result, with the exception that, in many instances, the bees built too much drone comb. As this is the principal objection, it is worth while to try to learn *why* bees build drone comb.

They build drone comb either to rear drones in it, or to enable them to store honey more rapidly. The question would naturally follow, *When,* and under what condition, do bees rear drones? They raise them only when they expect there will soon be queens to mate with them. Before swarming, bees always rear drones; i. e., if allowed to do so. If allowed to build comb at this time, it is always drone comb. Not only this, but drones are always reared in it *immediately.* I believe I have mentioned before in GLEANINGS, that one year, just before swarming began, I inserted an empty frame in the center of each of 25 colonies, and every frame was filled solid full of drone comb, and drones reared in almost every cell. When these colonies swarmed, many of the swarms were hived upon empty frames, and, with the exception of two swarms that had old queens, these swarms built no drone comb. Before the bees swarmed they knew that drones must be provided for the fecundation of the young queens. After they have swarmed they have a fertile queen, and no disposition to swarm; hence no drones are reared, *unless* the queen is old and the bees have in mind the superseding of the queen. In the old hives the drones hatched, and the bees filled up the frames of drone comb with *honey.* Although the drone combs were in the center of the brood-nest, not another drone was reared in them that season. If bees are allowed no drone comb before swarming they will rear drones in worker-cells. After they have swarmed they have no desire for drones, unless they are about to supersede their queen. Many have reported that their newly hived swarms built drone combs when the queens were *not* old. True; but look 'e here; *they didn't raise any drones;* they filled the drone comb with honey, which proves that they did not build drone comb for the purpose of rearing drones. Almost all who have reported trouble from the bees building too much drone comb have also reported that the bees stored honey in the drone comb; and when bees do this it is because they are gathering honey rapidly, and they can store it faster by building store or drone comb than they can by building worker comb; hence we must inquire *why* the bees store the honey in the brood-chamber instead of in the surplus-apartment. In my opinion, it is because sufficient inducement, or room, is not given in the supers. At the convention at Indianapolis, Mr. Bingham said that bees hived in an empty brood-nest of ordinary size would occupy and *fill* the brood-nest before they would go to work in a super furnished with fdn., and placed over said brood-nest. I do not feel inclined to take issue with Mr. Bingham, as I have never experimented in exactly that manner, and I well know that bees delight to work in a body. As I have many times explained, however, I do not hive my swarms in a brood-nest of ordinary capacity, but in one contracted to five L. frames, or to one section of Mr. Heddon's new hive, hence some of the bees *must* enter the supers. Another thing: I never put on supers only, with fdn. alone. The supers are *always* removed from the old to the new hive, and there are usually 56 one-pound sections in these supers, sometimes as many as 84, and the combs are in all stages of growth, from fdn. upon which the bees have just commenced work, to the finished sections. Not only is there an abundance of room in the supers, but the half-finished combs are a great attraction for the bees, as they furnish a place for the bees to store the honey they have brought with them, and only a little work is required to make room in them for the honey that is gathered. If these do not furnish sufficient room, another case of sections furnished with fdn. is placed between them and the brood-nest. In this way the bees are induced to *begin* storing honey in the supers; and where they begin, there they are apt to continue; thus there is no necessity, no *desire*, to build drone comb in the brood-nest in which to store honey. A queen-excluder keeps the queen below; and as soon as any comb is built she is ready with her eggs; and brood once started in a comb, it is continued to the bottom of the comb. The result is, that nearly all the honey goes into the super while the brood-nest becomes a brood-nest indeed.

Some one has reported, that putting the frames only 1⅜ inches apart, from center to center, would prevent the construction of drone comb. It may have a tendency in that direction, but it will not entirely prevent it when the bees *wish to raise drones;* at least, that is the distance apart I space my frames; and when the queens are old the bees will build some drone comb and raise drones in it. At the Indianapolis Convention Mr. Poppleton said this question was discussed in a lively manner at the Iowa State Convention held a short time previous; and of the dozen, or such a matter, who spoke upon the subject, five-sixths preferred fdn. to empty frames, as they not only were troubled with an excess of drone comb, but actually secured *less* honey when no fdn. was used. I can not understand this. My experience has been exactly the opposite. I do not claim to be any smarter than a great many "whole families," but I can not help wishing that I might be present when these brethren are having so much trouble. Mr. Poppleton suggested that there might be something in locality. With a slow yield, success would be more certain. There may be something in this; but we had a splendid flow last year from clover, and no trouble from drone comb. Perhaps some one will want to know what to do with old queens, if it is to their age that the building of drone comb is attributable. Candidly, I don't know. Of course, queens can be killed before they are old, and young queens introduced in their places, but I don't approve of this plan. It would necessitate considerable labor—more, I think, than would be profitable, considering the small amount of drone comb that will result from this source. It must be remembered, that queens are superseded at any time during the working season, and it is only when it occurs immediately after swarming that drone comb will be built.

I see friend Doolittle's "separator" article on page 939 calls for something from myself. This subject calls for more than a passing notice. To do it justice would make this article too long, so I will give my views in a future number.

W. Z. HUTCHINSON.

Rogersville, Genesee Co., Mich., Dec. 6, 1886.

Friend H., as my mind took in point after point in the above paper, I recalled to mind many facts of past experience to corroborate all you say; and in view of the above I am ready to admit that more surplus honey can be obtained by making the bees build their own combs in the brood-chamber, than by giving them frames filled with foundation. There are so many points to be observed, however, I am afraid many of the friends will be too hasty or too heedless to succeed as you succeed; but when it comes to a matter of dollars and cents, I think they will eventually learn to do it. It seems to me, however, there is going to be considerable danger of starving your bees after the honey-flow is over, if you don't look sharp, especially in localities like our own. Where we so seldom have honey-flows in the fall of the year, our bees are consumers, and producers to but small extent. The progressive bee-keeper, however, ought to be able to feed his bees promptly as soon as the flow of white honey is over, and I for one am not a bit afraid to be seen buying sugar to prepare our bees for winter. The great point seems to be to get all the marketable honey in surplus sections; and to do this, it seems to me quite likely the shallow frames are the ones to use.

THE DULL PROSPECTS FOR BEE CULTURE AND OTHER INDUSTRIES.

IS THERE A REMEDY?

IN the *Ohio Farmer* for Dec 4, there appears a short editorial in regard to the article in our issue for Oct. 15, page 812, on the low price of honey. I make the following extract from the remarks:

> This man took 600 gallons. If this is his year's crop, and he keeps four men at work, at a total cost of $3.00 a day, he ought to have at least $2 00 a gallon for his honey. He can't possibly get over one-fourth that price, net. He certainly *is* "in the ditch," and we don't wonder that Mr. Root calls upon the brethren to help him out.

May I call the attention of our friends of the *Ohio Farmer* to the fact that our Texas friend says he keeps four men at work, at a cost of $3.00 per day, and yet secured only 600 gallons of honey? If it takes four men 300 days in the year to secure such a crop of honey as mentioned above, I agree with our friend, that he is in the ditch—in fact, we are *all* in the ditch. But I am glad to be able to say that it is not true. Six hundred gallons of honey would be, even if it were of the very *best* quality, only about 7200 lbs., and we have hundreds of bee-keepers—yes, I think thousands—who can do all the work to secure a crop of honey of the above size, without any help whatever—not even so much as calling on their wives—yes, and have spare time besides. It seems to me the greatest trouble we have to face at the present day is getting into a fashion of calling an amount of work a day's work, that might be done by a good, energetic, go-ahead man in a couple of hours. A man may occupy the whole of a bright sunshiny day in doing his chores, and puttering around about something that really amounts to almost nothing at all. After he has got a knack of doing this he can readily find hired help that will do the same thing; in fact, they are pretty sure to pattern after their employer. Now, this course will kill any business. I do not mean to reflect on our Texas friend, for I do not know any thing about him. Possibly he may have hives so unwieldly, and so badly arranged, that it takes a great amount of time and expense to get the honey away from them. As this question is one of the vital ones before us, I should be glad if the friends, in sending their reports, would tell, as near as possible, how much it is worth to secure a crop. For instance, if you report having received six or seven thousand pounds of honey, tell us about how many days' work it took to get it, and what your time is worth per day, then we shall know where we are. Friend France, in his excellent article in this present issue, tells about taking from two to three thousand pounds of honey per day. Will he tell us how much per pound it cost to take it out of the hives, and put it into barrels ready for market? There is certainly a screw loose somewhere when we have reports like the one on page 812, and commented on on page 927, by friend Muth, especially if it took four men every working day in the year to get six hundred gallons of honey. Perhaps our friend had "the blues," and forgot to state that he had a large plantation besides, and the four men were kept a principal part of the time in caring for it. Mr. *Ohio Farmer*, wherever a farmer or dairyman or horticultural man can make a living, a bee-man can also.

TEASEL AS A HONEY-PLANT.

WILL IT PAY BEE-KEEPERS TO RAISE THEM?

THIS season, teasel did not yield much honey until basswood had entirely ceased. For that matter, I am not sure basswood gave me any honey this year. It was very little if any. When the basswood was all gone, and teasel had been in blossom about a week, I took two colonies for the purpose of testing the teasel-plant as a honey-yielder. From each stock I took away every thing in the shape of honey, brood, or comb. To No. 1, I gave 5 frames of old empty comb, and as many 1-lb. sections (filled with fdn.) as I could get on. In 17 days (or about that) they had filled 48 sections, and capped almost all of them all up nice. I took one frame of sections (8) that were all done, and replaced them with empty ones, some time before the 17 days were up. These were drawn about two-thirds out, but not capped at all, and are not counted in with the 48. Besides this they filled the five frames I gave them, with brood and honey.

Colony No. 2 I tiered up with empty combs, and saved their honey to give stocks to winter on, so I might test it there also. In quantity they produced about equally with No. 1. Teasel honey, when first gathered, is very thin, and requires a good deal of evaporating before it is capped over; but when allowed to ripen fully I know of no other honey that is its equal.

At the time I was testing with my two stocks, my friend G. M. Doolittle repeatedly told me his bees were getting scarcely a living. This proves to me that bees can not work profitably where they are obliged to fly long distances for their stores. Mr. D. lives about two and one-half or three miles south of me, and there were but few teasels after going one-half mile south of my place, making virtually no teasels nearer Mr. D.'s apiary than two miles; while within one and one-half miles I believe my bees had one hundred acres.

One can easily tell when bees are working on teasel by the white dust that adheres to them. The honey is pure white, and in market generally passes for basswood, though where known it is preferred. Whether teasel could be profitably grown for honey alone, is a question. I do not believe that any thing less than 20 acres would amount to much to an apiary of 100 colonies; but possibly it might do to sow seed in waste places, or on broken land, and let Nature do her work. As a plant, if not dug up, it will remain and grow until it gets large enough to run, even if it is five years. If desired, they are easily killed, either by plowing or mowing before the seed ripens.

C. M. GOODSPEED.

Thorn Hill, N. Y.

"THE QUEEN OF THE HOME."

HOW WE CAN LIGHTEN HER LABORS.

THE following kind letter from Dr. Miller was not intended for publication, as you will see; but as it comes so directly in line with Mr. Terry's and Prof. Cook's recent articles upon home conveniences we give place to it here, with the hope that it may work good in the home.

I want to thank you for advertising and selling such a fine carpet-sweeper. We have not been without a carpet-sweeper in the house for a good many years. One or two have given out, and the last one has been lying idle for about five years, a serious fault being that it too closely resembled a reaping-machine in the noise it made. But this new one I bought of you so much excels any thing previously used, that my women-folks are very enthusiastic in its praise. You are so much given to sticking out in every direction, expected and unexpected, that I wonder you have not made a vigorous attack upon all your readers who have wives not yet provided with a good carpet-sweeper. Few husbands realize, I think, how much *real hard work* their wives have to do in the way of sweeping; and if they knew the difference a good carpet-sweeper makes, there are few of them who care so little for their wives' comfort as to let them go on the rest of their lives with aching arms, daily wrestling with a broom.

I haven't time just now to write any thing for GLEANINGS; but if I had, I don't know but I should try in some way to wake up the men on this sweeping business. May be you can do it. Call their attention to the number of hours spent in sweeping; get them to try it themselves; tell them how much fine dust, bits of wool, etc., are breathed into the lungs when the broom is used, and which the carpet-sweeper keeps all to itself; the labor saved in dusting, etc., not forgetting to let them know that a broom must still be used in corners which the carpet-sweeper can not reach. If they can not get at home such a one as you sell, they had better pay heavy carriage, and buy one from you; for many of them are only a nuisance. I think I paid $3.00 or $4.00 for one not half so good as yours.

That 10-cent honey-knife is the finest thing I ever used for cutting out bits of comb, etc., while the colony is in the hive. C. C. MILLER.

Marengo, Ill.

Friend M., I am very glad to be able to say to you and the other readers of GLEANINGS, that the manufacturers have made us such an offer on carpet-sweepers for the coming year, providing we purchase a very large quantity during the dull season, that we can furnish a machine, greatly improved, for only $1.50, instead of $2.00, as heretofore.

THE LAW RELATING TO BEES.

SOMETHING FROM ONE OF OUR LEGAL FRIENDS IN REGARD TO FORMER DECISIONS, ETC.

THERE are no statutes and but little law relating to bees as bees; therefore in treating of the subject we must employ such of the analogies as are to be found in the principles relating to beasts and animals.

OWNERSHIP.

The original source of ownership in law for these and all other things of property, is found in the first chapter of Genesis, the 26th verse, whereby man is given "dominion over the fish of the sea, and over the fowl of the air, and over the cattle, and over all the earth, and over every creeping thing that creepeth upon the earth." This is the first great law of property.

Following this, ownership in bees was first, and still is, acquired by occupancy. Occupancy gave the first (human) right to lands, movables, and bees, and is the natural rational method, *a priori*, of acquiring title in them; and upon this principle of universal law this title continues so long as occupancy continues.—*2d Kent Com., 374.* This is the basis of obtaining title to wild bees, by first reducing them to our possession, and subsequently keeping them in our custody.

The other mode, of getting title through the operation of contract of sale and purchase, is too familiar to need description; yet we find a few decisions, mainly in the New York courts, relating to this article of property, from which we extract, by brief quotations, the special points decided:

"Although an unreclaimed swarm of bees belongs to the first one who hives them, yet if a swarm fly from the hive of a person, his qualified property continues as long as he can keep them in sight, and has power to follow them."—*15 Wend., 550.* "And if they are taken or destroyed by another, although on his own land, an action of trespass (or trover) may be maintained against him therefor."—*1 Root, 209; 7 John., 16.*

"*Wild bees*, in a bee-tree, belong to the owner of the soil where the tree stands." "Though another discover the bees, and obtain license from the owner to take them and mark the tree with the initials of his own name, this does not confer the ownership upon him until he has taken actual possession of the bees." "If he omit to take such possession, the owner of the soil may give the same license to another, who may take the bees without being liable to the first finder." "Both parties having license, the one who first takes possession acquires the title."—*1st Cow., 243.*

If the first licensee *pay* for the bees, he would have become the owner, as that event would have changed the ownership of the property, as well in a tree as if they had been in a hive.

AT SWARMING-TIME.

We may not only reclaim our bees so long as we keep them in sight, but may follow them upon our neighbor's land, and retake—being responsible to him for the *actual* damage—no more.—*14 Wend., 237.*

DAMAGES FOR BEES IN HIVES.

As this is the most fruitful source of discussion and contention against keeping bees, we cite all the authorities at hand, beginning at the earliest decisions, and ending with the latest.

"An injury received at *night* is only at the fault of the party injured."—*M. & M., 505.*

"Vicious animals may not be placed in or on the approaches to the house, so as to injure persons exercising a lawful purpose in going along those paths to the house."—*19 Eng. Com. L., p. 394.*

"*Posted notice* is advisable, and will put persons upon their guard, and make it at most their own misconduct if injury comes of hitching teams, etc."—*Chit. Pl., 82.*

"Owners of private property are not liable for injuries occurring, when those injured were upon premises without permission, and not on business, etc."—*25 Mich., 1.*

WORKING BEES ABROAD, IN STORES, ETC.

In case of grocers and others dealing in honey and other sweets, which naturally attract bees, and by means of which the bees are destroyed, the owner of the bees may as well have action for injury to his bees, as for the merchant to claim indemnity from their annoyance, or pay for his sweets." "Where an injury, of which a plaintiff complains, is the result of his own fault or negligence (in unnecessarily exposing his wares), or of the negligence or fault of both parties, without intentional wrong on the part of the defendant, no action can be maintained."—*2d Mich., 259; 10, id., 193.*

IN FIELDS, VINEYARDS, ETC.

In responding to allegations of injury in this branch of the subject, the right "to recoupe" (to cut again) is applicable; and "in law this signifies the right and the act of making a set-off."—*Bouv. Dict., 430.* In law this is regarded as an equitable right, and it would afford a fine case of litigation to put such a case into a court of equity, and establish as a fact that more benefits were done by bees to the blossoms of trees, vines, and grain, by the distribution, etc., than in the supposed injury to the mature fruit; yet such is the spirit of equity and the office of recoupment.

INJURIES TO ANIMALS, ETC.

Upon this point, the latest, fullest, and best adjudication to be found is in the case of *Earle vs. Van Alstine* (*8, Barbour's Reports, 630*), being the unanimous decision of the Supreme Court of New York as announced by Justice Samuel L. Selden. In this cause the complaint alleged that the defendant was the owner of fifteen hives of bees, which he wrongfully kept in his yard, adjoining the public highway, and that the plaintiff's horses, while traveling along the highway, and passing the place where the bees were kept, were attacked and stung by the bees so severely that one of them died and the other was injured, etc. The answer denied the charge contained in the complaint. Trial was had in justice's court, and judgment given plaintiff for $70.25, and cost. This judgment was reversed in the County Court, and from this judgment plaintiff appeals to the Supreme Court. The two questions involved, as stated by the court, were:

"1. Is any one, who keeps bees, liable at all events for the injury they may do?

"2. Did the defendant keep these bees in an improper manner or place, so as to render him liable on that account?"

After a full statement of the case, and a critical examination of the authorities, the judge says:

"These authorities seem to me to point to these conclusions: 1. That one who owns or keeps an animal of any kind becomes liable for any injury the animal may do, only on the ground of some actual or presumed negligence on his part. 2. That it is essential to the proof of negligence, and sufficient evidence thereof, that the owner be shown to have had notice of the propensity of the animal to do mischief. 3. That proof that the animal is of a savage and ferocious nature, is equivalent to proof of express notice. In such cases notice is presumed.

"Having shown, then, as I think, clearly, that the liability does not depend upon the classification of the animal doing the injury, but upon its propensity to do mischief, it remains to be considered whether bees are animals of so ferocious a disposition that every one who keeps them under any circumstances does so at his peril. If it is necessary for the plaintiff to aver and prove the mischievous nature of the animal, nothing of the kind was done in this case; but if courts are to take judicial notice of things so familiar to man as bees, which, I suppose, they would be justified in doing, then I would observe, that, however it may have been anciently, in modern days the bee has become almost as completely domesticated as the ox or the cow. Its habits and its instincts have been studied, and through the knowledge thus acquired it can be controlled and managed with nearly as much certainty as any of the domestic animals; and though it may be proper still to class it among the *feræ naturæ* (wild by nature), it must nevertheless be regarded as coming very near the dividing line; and in regard to its propensity to mischief, I apprehend that such a thing as *serious* injury to persons or property from its attacks is very rare, not occurring in a ratio more frequent, certainly, than injuries arising from the kick of a horse or the bite of a dog.

"There is one rule to be extracted from the authorities to which I have referred, not yet noticed; and that is, that the law looks with more favor upon the keeping of animals that are useful to man than such as are merely noxious and useless; and the keeping of the one, although in some rare instances it may do injury, will be tolerated and encouraged, while there is nothing to excuse the keeping of the other. In the case of *Vrooman vs. Lawyer* (*13 John., 339*), the court says: 'If damage be done by any domestic animal *kept for use or convenience*, the owner is not liable to an action without notice' (of their being vicious, etc.). The utility of bees, no one will question; and hence there is nothing to call for the application of a very stringent rule to the case. Upon the whole, therefore, I am clearly of the opinion that the owner of bees is not liable at all events, for any accidental injury they may do.

"The question is still left, whether the keeping of these bees so near the highway subjects the defendant to a responsiblity which would not otherwise rest upon him. I consider this question as substantially disposed of by the evidence in the case. It appears that the bees had been kept in the same situation for some eight or nine years, and no proof was offered of the slightest injury ever having been done by them. On the contrary, some of the witnesses testify that they had lived in the neighborhood, and had been in the habit of passing and repassing frequently, with teams and otherwise, without ever having been molested. This rebuts the idea of any notice to the defendant, either from the nature of the bees or otherwise, that it would be dangerous to keep them in that situation; and, of course, upon the principles already settled, he could not be held liable. The judgment of the County Court must be affirmed. Judgment affirmed."

See this case in *Thompson on Negligence, Vol. I., pages 182-'8*, and authorities here cited.

The foregoing is probably sufficient to elucidate the principles of law specially applicable to the peculiarities of these useful insects; leaving the other more common principles of the law to be applied as in other matters. Before quitting the subject, however, we must remark that it is the best of wisdom in such matters, as in all others, to avoid litigation wherever and whenever substantial justice can be received or done, without the intervention of the courts; for the law is, at best, hardly more than a two-edged sword—*cutting both ways.*

HARMON SMITH, ESQ.,
Ionia, Mich. Attorney and Apiarist.

The above, although it does not touch the question very much of bees and grapes, serves to give us something of an idea of what may be expected where we go to law to settle these differences; and I heartily indorse the concluding words of friend Smith, reminding us that whoever decides to go to law will probably find it a two-edged sword indeed, and that *both parties* will probably get cut more or less.

HOW TO WIN.

BY ONE OF OUR BEE-KEEPING FRIENDS.

A RECENT number of *The Northwestern* contained a very appreciative notice of a royal book by a royal woman —"How to Win," by Frances E. Willard. The writer carefully read the chapters of this book as they appeared in the *Chautauquan.* They were of deep interest to her, not only because they were prepared by a dearly loved teacher, but also she herself wished to learn "how to win." It seems to her that Miss Willard, in telling the girls "how to get on in the world," did not emphasize one fact strong enough. She did not speak of the little paths of opportunity leading directly from home to broader avenues. She did not tell them that, before they tried to climb into teaching, telegraphy, type-writing, medicine, law, journalism, or literature, it would be well for them to find out whether the first rounds of the ladder to success did not rest just beneath or just above the sod of their own dooryards.

The windows of the room where these words are written look into a strange little city, where a certain girl of our acquaintance has found her kingdom. Grass grows thick and unbroken in the narrow streets which never echo to the whistle of the locomotive, the jingle of a street-car bell, or the roll of carriage-wheels. The small, queer houses differ in size, but in one thing they are all alike; they have no windows and only one door. The people who hourly pass from or enter these doors are the most industrious on earth. In spite of the fact that they are able to wear a suit of brown and gold velvet trimmed with the most filmy and delicate lace imaginable, every day in the year, they are not too proud to work for their living. They abhor strikes, never waste a moment of time, and loyally and royally give to their young ruler enough of the sweets gathered from a thousand flowers to fill the capitol building. For this girl rules a kingdom of bees, and her profession is that of a honey-raiser. In learning how to win in this direction she has not found it all sunshine, and there have been times when she feared she might be able to write a chapter on blasted hopes, from practical experience.

She began on two or three swarms, and the first year yielded lessons learned only through failures. She was very much afraid of bees, and they stung her cruelly because she, in her ignorance, trampled on their rights. The second year, both stings and failures were less numerous, but the outgrowth of her colonies caused expenditure a little over receipts. The third year the balance in her favor was not large, but she had gained greatly in judgment and qualities which make up a good bee-keeper, while her business gave her delightful chances to study God's marvelous planning for the life and work of even his tiniest creatures. This fourth year her honey-house is filled with luscious honey. There are hundreds of pounds waiting for shipment to distant cities, besides other hundreds which have gone before. As you take one of the cakes, and the light flashes through it, you realize that the bee has made the myth of King Midas' golden touch a reality. It has caught the clover-blooms, and in these transparent cells changed them into gold.

How did this girl earn her success? She kept at it, refusing to be discouraged, even when friends counseled retreat and a withdrawal from the business. She compelled herself to learn her trade as thoroughly as if she were a carpenter, a blacksmith, a painter, or mechanic; and in doing this she studied closely the best books and magazines on the subject of bee-keeping. Realizing that as a learner she ought to begin with the alphabet of her profession, she sent for an "A B C of Bee Culture," and her earnest, faithful study of that rich cyclopædia of "every thing pertaining to the care of the honey-bee" now reappears in returns from Chicago, Milwaukee, and Kansas City.

To keep abreast with the improvements in her profession, to take in the new thoughts of the students, and to have a bond of union with the large circle of little workers, our bee-keeper added to her A B C the magazine, *Gleanings in Bee Culture*, to which she owes much of her success. We who skip the technicalities, and dip into bee details just a little for our bee-keeper's sake, have learned to love and look for *Gleanings*, because it helps us, bee-magazine though it is, to learn how to win the kingdom of heaven. MRS. LYDIA STRAWN.

Ottawa, Ill.

We extract the above from the *Northwestern Christian Advocate*, of Dec. 1. The moral to the little story is excellent, and we bid those A B C scholars who feel disappointed because they have not taken in more money than they have paid out for the first year or two, to read the story and take courage.

SEALING HONEY-TUMBLERS, ETC.

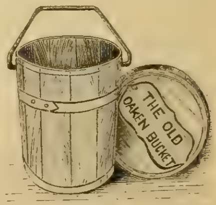
HOW TO MAKE THEM ABSOLUTELY AIR-TIGHT, AT AN INSIGNIFICANT COST.

AT the Michigan State Convention a little idea came up that was well worth the whole expense of time and attendance. As a matter of course, honey pails and tumblers were on exhibition, containing samples of honey. Now, even experienced bee-men would every little while tip a tumbler over on its side, and the honey would ooze out under the edges of the cover, daubing the tables, the fingers, and clothes of the bee-friends. Secretary Cutting finally asked permission to tell the convention how to obviate all these troubles; and when he told it I felt like giving an Indian war-whoop of exultation, although I did not dare to do it just then and there. The plan is, briefly, this:

Get a cheap wire sieve of coarse mesh. Those we have on our ten-cent counter will do; or the transplanting-frame on page 136.

Put this frame or sieve on a couple of boxes, so as to raise it high enough to set a coal-oil stove underneath. I believe that friends Cutting and Mason, at the Tri-State Fair, used the part of an uncapping-can to which the wire cloth is attached. Now turn your glass tumblers or pails bottom up over the wire cloth, and arrange the heat so they will gradually get warm enough to melt beeswax. Then dip them in melted wax, kept in some pan over another lamp. The wax in this latter pan should not be over one-fourth or one-eighth of an inch in depth. Dip the mouths of your tumblers in the melted wax, holding one in each hand, but don't turn them right side up until the wax has cooled enough to prevent it from running down the sides. With a little practice you will find you can very rapidly put a nice ring of wax evenly over the mouth of every glass pail or jelly-tumbler. As the glass was warm when it was dipped, there is no possibility of the wax cleaving from the glass. This arrangement is for cups and pails having a cover that slips over the top. It works especially well on the "Old Oaken Bucket" glass pails that have been sold so largely, a cut of which we give:

In putting on the covers we must warm *them* up to the point where they will melt wax; and this is done with the same apparatus used to warm the glass pails. After a lot of your pails are coated with wax, as described, fill them with honey up to within a quarter of an inch of the top; or you can, if you choose, weigh out a certain amount of honey in each tumbler. Of course, you are not to daub any honey on the sides, nor get any on the beeswax; for if you do, it will spoil the plan. Take one of the hot tin covers and slip it over the pail, just as if no wax were on the rim at all. The cover should be warm enough to melt the wax as it goes down. It will then be sealed up so perfectly that you can roll the package on the floor, if you choose, or hold it upside down as much as you like.



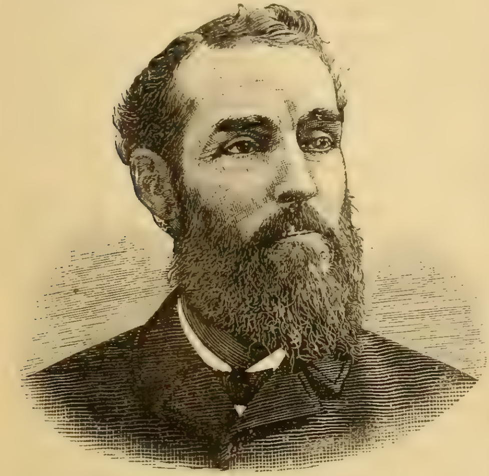
"OLD OAKEN BUCKET" GLASS HONEY-PAIL.

Friend Cutting said the credit of the invention belongs to Dr. Mason, of Wagon Works, near Toledo; but Dr. Mason very modestly disclaimed any credit for the invention, saying that he read a description of the process in back numbers of GLEANINGS. I promptly replied, that no such thing had ever been given in our pages. Then he said it was in the *Canadian Bee Journal;* but our genial friend McPherson, who represented Canada and the *C. B. J.*, replied as promptly, that he was sure no such thing had appeared in *their* pages. Now, then, friends, if any one can tell us where this matter appears in print, providing it has *ever* been in print, we shall be glad to "render unto Cesar the things that are Cesar's." If we can not find any such place, I think Dr. Mason and Secretary Cutting will have to bear the honor. It is a most simple thing, it is true; but I have experimented and puzzled my brains for years to decide upon some cheap method of sealing up jelley-tumblers with beeswax. The trouble was, it never occurred to me to put on the wax *before* I put in the honey. While we are on the subject, I may remark that we can furnish the Old Oaken buckets of 1 lb. for $4.50 per 100, or $40.00 per 1000.

SOME OF GLEANINGS' CONTRIBUTORS.

TAKING A LOOK AT THEIR FACES.

IT is a rare pleasure to meet, face to face, those who have written for the pages of any periodical we love. This has often occurred to me when attending the various bee-keepers' conventions. Well, the next best thing—that is, where we can not meet them face to face—is to see their faces illustrated through our journals; and we take pleasure in submitting to you the picture below—a very good one of our friend T. B. Terry.



T. B. TERRY, THE POTATO MAN.

Mr. Terry is pretty well known to the readers of GLEANINGS, through his articles here and elsewhere. He commenced on a poor farm, with only little capital to start with, unless it was an education a little better, perhaps, than the average young farmer has; faith in himself, and a determination to make his way by his own strength of muscle and vigor of brain, and last, but not least, by the hearty co-operation of his good wife. The great feature of Mr. Terry's life, and the one that has made him sought after by different States to address farmers' institutes, is the fact that he started in the outset to see if the labor and drudgery of farmwork could not be shortened and made easier by better tools and better methods of management. Our friends who read the *Ohio Farmer* will notice that our friend Terry has been pretty severely pulled to pieces, especially in regard to this matter of improved tools; but he seems to be abundantly able to keep up his side of the argument, especially while he has his own small farm, his own stock, and his own tool-house full of tools to back him up. It is not theory that friend Terry writes—it is actual experience, and the fruits of earnest, faithful, hard work. He is heartily in love with his farm and farmwork, and his love and enthusiasm are so contagious that one can scarcely read his writings without wanting to be a farmer too. I did not know till just now that friend Terry was with me on the tobacco question. But I might have known it; for how could a man in these times be progressive, and be a tobacco-user?

HOW I FIXED MY BEES FOR CELLAR WINTERING.

RAISING COMBS SO AS TO LEAVE TWO OR THREE INCHES OF SPACE UNDER THE BROOD-FRAMES.

HAVING my bees in the cellar, fixed to suit me, I thought perhaps the readers of GLEANINGS might like to know in what manner I had them prepared. The doors to the cellar were left open for two weeks before I set the bees in, so as to cool the cellar off as much as possible, for, as a usual thing, the temperature is too high if I do not do this. A day was chosen for setting in, which was mild, and a little above the freezing-point, so that the hives would come off the bottom-boards without snapping, so as to irritate the bees. I also find that bees are less easily disturbed in such weather than they are when it is colder. Before setting the first one in I placed a bottom-board on the ground, and upon this I set a cap, or cover, to a hive, so as to raise the hive a little distance above the cellar bottom, on account of damp and impure air. On top of this cap was spread a part of a newspaper so as to keep the droppings from the bees off the top of the cover; for I have found there is nothing that will spoil the paint quicker than will these droppings. On top of this paper I placed a rim, or frame, made by nailing four pieces of half-inch stuff, which was 3 inches wide, together, so as to be the same size as the bottom of the hive. On this rim the hive is placed, which gives about 4 inches of space between the bottom of the hive and paper below, for plenty of room for dead bees to drop, and for fresh air to circulate.

Before setting in the cellar I made a sawdust cushion as follows: A rim was gotten out, the same as that upon which the hive is placed; and upon one side of this was tacked a sheet of cotton cloth, which cost only 5 cents per yard. To hold the cloth securely to the frame, a strip of the same was torn off and folded so as to be three double, this being placed on top of the sheet, along the edge, so as to clamp the sheet between it and the frame when the nails were driven. After nailing on the first sheet the rim is turned over and filled with fine dry basswood sawdust, which was saved when sawing sections last winter, the sawdust being well packed down. Now nail on another sheet the same as the first, and the cushion is made. Before putting this on the hive I took off the quilt, or honey-board, and substituted two sheets of this same cotton cloth; for from the experience of the past three winters I find that such is much the best, as it allows the moisture from the bees to pass off, yet keeps the bees dry and nice. Especially do I find this so in cellar wintering. As it takes only one yard of this 5-cent cloth for one of my hives, the expense is very little; while the cushion will last for a lifetime, if properly cared for. When the hive is set in the cellar a sheet of newspaper is spread over the cushion, the same as was the one on top of the cap, when another rim is placed on this, and we proceed as before. The cellar is high enough to pile four on top of each other, and wide enough to place three tier side by side, but I set only one tier on each side so as to leave an alleyway in the middle, so I can inspect them at any time I may wish, for I always go into the cellar twice a month to see that all is right as to temperature, mice, etc.; and at these times I can not help looking at the little fellows, for the fun it gives me. I know some insist that this is all wrong; but I could never see that it did any harm; and even if I did, I doubt if I could deny myself this pleasure, for I keep bees for pleasure as well as profit, often thinking that the pleasure part pays the better. Well, after all are in, the cellar is closed, when it is managed as I told you about last winter.

G. M. Doolittle.

Borodino, N. Y., Nov. 26, 1886.

Friend D., in regard to raising the bottom-boards for wintering, I would add that friend Bingham, at the Michigan State Convention, stated that he did not know of any other one thing that had given so good results as raising combs two inches or more from the bottom-board. This allows dead bees and debris to drop down through out of the way; allows plenty of air to pass all around under the comb, and seems to be a safeguard against the effects of dampness and impure air. He uses this space below the combs, whether they are outdoors or in the cellar; and he has of late been very successful in wintering with little loss.

OVER 20 TONS OF HONEY, AND HOW TAKEN.

When Honey is Sufficiently Ripened to Extract.

VALUABLE SUGGESTIONS FROM E. FRANCE.

After selling off 55 colonies of bees we had 395 colonies to commence with in the spring. We increased by dividing until we had 507 colonies in the fall. We commenced to extract honey June 3d, and finished on the 5th of July. Amount of honey taken was 42,489 lbs.—an average of very nearly 108 lbs. per colony, spring count. The bees were in six apiaries—one apiary at home; the other five were from 4 to 7 miles away, in different directions. We worked one apiary a day every day except Sundays and the 3d day of July. But all the boys were hired to work on the 4th of July, or the day on which the Fourth would be celebrated, as this year it came on Sunday. Boys don't like to miss the Fourth of July, and so they proposed to have me let them work three apiaries in two days, and then have the day gained to go to the celebration. I agreed to that. Now, if ever you saw a set of boys work to gain time, you can form some idea how those boys worked.

On the first day of July we were up and off, and drove 5 miles to the yard to work; got there as soon as it was light enough to work. We put up the tent and extracted 1800 lbs. of honey, and then drove home, unloaded the honey, ate our dinner, and then drove to another yard, 5 miles away in another direction; got there at 5 o'clock P. M. We worked half of the bees, and then drove home with 1200 lbs. of honey. The amount taken, after five o'clock, by daylight, made 3000 lbs. extracted in one day, and we drove 20 miles in going and coming to and from our work.

The next morning at daylight found us 7 miles from home at another yard where we extracted 1400 lbs., and drove back home to dinner. After dinner we drove back to the yard that was half worked the day before, and took 829 lbs., and were home again before sundown, having taken out that day 2229 lbs., and traveled 24 miles. I think that was pretty good work for boys. I ran the extractor both days myself—a two-comb machine. We keep one extractor at each yard during the honey-harvest, and don't move them from one yard to another.

I make our own extractors, as I can not buy one to suit me. I make them in the winter, when I have plenty of time, then they don't cost as much money out as it would to buy them. From the time that I commenced to use the extractor up to the year 1884, we emptied the combs once in 10 days; but the three last years we have emptied them just once a week, or 7 days. We find the seven-day plan decidedly the best one. We get more honey, and I can not see but it is just as good. This dry season we could have extracted as often as four or five days, and the honey would have been all right. Last year was very wet, and our honey was about one-fourth capped when we extracted it, and the honey was rather thin. This year the combs would be, on an average, three-fourths capped, and were thick—in fact, thick enough as fast as gathered. Another reason why I like the seven-day plan is, we are not troubled with the bees getting the swarming fever. They get their combs just nicely filled in our large hives, in seven days, and then we come and empty the honey. The queen then has room to deposit her eggs, and the bees have plenty of room to store their honey; and then they are all happy and contented, and won't swarm. We use the Langstroth hive, three stories high, for the extractor, with eight frames in each story, and we don't think it is any too big; and, by the way, we are wintering some of them three stories high outdoors—the top story a solid block of honey.

We don't practice any method of ripening our honey by artificial means. We take our honey-barrels right into the field with us; fill them, drive in the plugs, take them home, and store them in our honey-house, standing on end, with the plugs up. We put the honey in through an inch hole, with a funnel. We pack the barrels away without loosening the plugs, just as they come from the fields, and I think the honey keeps better than it would to give it air. It is put in warm, in the heat of the day, and will not swell by cooling. Keep it tight, and it will, I think, retain its flavor better than to give it air. I know the honey will remain longer without candying if kept tight.

REPORT FOR THE LAST FOUR YEARS.

Average amount of honey obtained the last 4 years is 103 lbs., spring count.

No. colonies spring of	1883, 211.	Average,	104½ lbs.
" " "	1884, 285.	"	109 "
" " "	1885, 320.	"	91 "
" " "	1886, 395.	"	108 "
Average amount for the four years,			103 "

For so large an amount of bees for so long a time, we think that is a pretty fair report. The bees have all been wintered on their summer stands, with a steady increase in the number of colonies.

THE RECORD OF TWO STUDENTS.

As I said at the beginning of this article, we sold 55 colonies, last spring, to a couple of our students, one of them buying 4 and the other 51. The boy who bought the four got 117 lbs. average of honey from the four. The other lot of 51 was hauled 9 miles on lumber wagons, without springs, over a very rough road, then unloaded in my pasture-lot. He commenced to move them March 19, and moved when the roads were passable. Most of the bees were moved the 14th and 15th of April. On the 21st day of April, and the following night, the bees were all loaded up again on lumber wagons, and moved 1¼ miles, and put on a car. The next day I went with them to Brodhead, 80 miles, then again they were moved one mile and set up and turned loose to work in a new location. One of the hives had a leak in it. As they were packed in a cattle-car, I could not get to them to stop the leak; and when we opened it there were only a few young bees in the hive, so we put the brood-combs and young bees in with another swarm.

One colony swarmed out and went off, leaving him 49 colonies to commence with. From these he extracted 9880 lbs. of honey—an average of 201 lbs., spring count—a pretty fair record for a boy, for his first year, by himself.

A GOOD REPORT FOR BLACK BEES.

It seems to me I hear you say, "They must have been a pure strain of Italians, or some other fancy breed." Well, they were a pure race of blacks, or brown bees, as you choose to call them—those fellows that some writers say "live only from hand to mouth"—poor despised blacks. They are not so poor a bee, after all. Who has got 49 colonies of any other race that has done any better (take a whole apiary through, not pick out 49 of the best)? Do I think the brown bee is as good a honey-gatherer as the Italian? Yes. I don't think there is very much difference, and I have been handling them both for several years, and have had several strains of Italian bees in that time. I am sure that there is more difference in a location for an apiary than there is in the race of bees. Take, for instance, that same lot of bees that I sold and moved to Brodhead, this last spring, where they were before I moved them. They never gave as good an average as my other apiaries. They had plenty of basswood, but were short of clover. In their new location they had plenty of white clover, and a fair range for basswood besides. As the weather was so dry, and he had only the one apiary to attend to, he extracted oftener than I have ever done, and that made a big difference in the amount of honey gathered. Perhaps the Italian bee in the same place, and handled the same, would have done as well, but I don't think they would have done any better, so you see the Italian is not a favorite with me. I have a good many pure Italians and a good many more—hybrids, I think. The hybrids are the best workers; and as for their stinging qualities, they can do their share of it. The brown bees are the most peaceable, and less liable to sting, of any bees I ever had.

Now, I know that I may be treading on somebody's sore toes, but I can not help saying just what I think. I wish I could get a race of bright Italians that are as peaceable to handle as my brown bees, and I am ready to give $25.00 for a queen or queens from which I can raise those bright Italians that will be as peaceable, and as good honey-gatherers, as my brown bees. Why? Because we have about as many bees as we care to handle, and would like to sell off our increase, and I think Italians would sell better.

I have some other things to say at some future time. I will just say here, if any one wants my views on any point in the bee-business, let me know what it is. EDWIN FRANCE.

Platteville, Wis.

Many thanks for your excellent report, friend F., and we are very much obliged to you for this last invitation. In accordance with it, I want you to tell us about that home-made extractor that suits you better than any you can buy. Tell us how it is made, and your objections to those that are in the market.—Barreling your honey, and bunging it up just as it is taken from the hives, would be in accordance with friend Bingham's views. I believe you are right in saying that honey that is corked or bunged up will keep longer without candying. Doubtless you remember what has been said about the crop of alsike-clover honey which we found at the Columbus State Fair. Well, we are greatly surprised that, even after our zero freezes of late, it has not candied a particle. You can cut it with a knife, and it is really liquid amber, but no candying.—I am very glad indeed to know that you have succeeded so well in teaching the boys who help you, that they make the excellent report you give us. Yes, I am glad to get it, even if it *is* a good report from black bees. But, look here, old friend; even if you have found as good results from black bees as from Italians in the way of honey, how about repelling moth millers—repelling robbers, and ever so many other points that have been brought out in the last 20 years? Never mind about treading on toes. We will pull our toes back out of the way, if you get to tramping too close and too hard. At the recent Michigan Convention there was some talk about rearing black and hybrid queens for those who prefer them, and I replied that we were ready to supply all demand at the Home of the Honey-Bees; that is, when it is settled that anybody wants blacks and hybrids in preference to Italians.

A GOOD REPORT FROM SOUTHERN IOWA.

ITS FLORA AND RESOURCES.

I HAVE located here in the southeast part of Page Co., Iowa. I came here last March, hence I have had the opportunity of noting the character and result of the past honey-season. The people here claim that it was a very poor season, on account of the extreme drought that prevailed, lasting from June 9th until Aug. 13th. This had the effect to cut short, somewhat, the clover and basswood yield. It also impaired the growth and development of the autumn and fall flowers. The fall rains resulted favorably to the secretion of nectar, and, as a result, bees are in a good condition for the approaching winter. My yield for the season was 121 lbs.; clover and basswood, and 96 lbs. autumn. Total, 217 lbs. per colony, for the season.

If I am not mistaken, this is an excellent place for bees and honey. The industry, however, has been neglected, as nearly all use the box hive, or some substitute. I brought fifty Simplicity hives in the flat with me when I came here last spring. Forty-one of these are now in the hands of my neighbors. Many never saw a movable-frame hive with metal bearings before, while wax sheets and their manufacture was an unheard-of wonder. People came for miles around to see the extractor work, and get a glimpse of my fixtures and mode of handling bees. One gentleman came three miles, and offered me two dollars to show him a queen-bee. Of course, I showed him the queen, and he saw her depositing eggs as any good queen should. You can rest assured that he went away highly pleased, and I allowed him to take his two dollars along too.

I will give a condensed list of the honey flora of this section of country. First, the sources, constituting the spring flora.

The soft maple comes first. This is followed by the different species of willows, which exist here in great abundance; then comes a great array of minor prairie-flowers, followed by the box-elder, which is very plentiful. Then comes fruit-bloom, which is a bonanza, besides our cultivated orchards, of which we have a full supply. There are 1000 acres of timber within a radius of 2½ miles of me, which is literally thatched over with wild-cherry, plum, crab-apple, and white-thorn. When all this comes into bloom, I doubt not that it makes both the bees and bee-keeper rejoice.

Here the spring flow closes, and we find that it has run into the lap of the summer flow, for white clover is now in bloom, being about May 20. Basswood opens about June 15th, right in the midst of the clover. Then comes a rush of honey, lasting until July 1st. Here the summer flow steps down and out; and a lull of two weeks ensues. Then comes the autumn flow, which is ushered in by the blooming of the buckbush, a very good honey-shrub, and very plentiful. A week later we are met with a bright yellow flower that seems to be a near relative to the noxious Spanish-needle, yet it lacks the needle, and is quite distinct from that variety. From this the bees are found bulging their combs with a bright golden-colored honey. A week later comes heart's-ease, which seems to give still better results. This continues in bloom until the last of September, and is here very plentiful; in fact, it is a great nuisance to farmers. In the meantime a great array of autumn prairie-flowers are in bloom, many of which seem to furnish considerable honey. Notably among these is the prairie-locust, that grows in great profusion.

The fall season closes with the various species of fall asters. These furnish a good flow of honey when atmospheric conditions are favorable. The honey season closed here this season Sept. 29th. The aster family furnished no honey—weather conditions not favorable. R. B. ROBBINS.

Siam, Iowa, Nov. 24, 1886.

Friend R., as you state it I should say that your locality is a most excellent one. It is very rare that we find three great sources of honey all in one place; namely, fruit and apple trees, white clover, and basswood. When we have added to this the yield from autumn flowers—that is, if you have this every season—you have a remarkably favorable location. Two hundred and seventeen pounds to a colony is certainly excellent; but you do not tell us how much of an apiary you had.

FRIEND TERRY ON TOBACCO.

HE STARTLES US BY SOME NEW FACTS.

FRIEND ROOT:—It is with a great deal of pleasure that I read, in each number of GLEANINGS, the Tobacco Column. I am glad to know that one man is doing all he can to check this filthy and disgusting as well as expensive habit that is now so widespread in our beautiful land.

Some experiences lately have made me think more than usual about tobacco and its victims. I called on a family, not long since, who are said to be very much in need of help. They hadn't any oil to burn, but the man kept up his steady spit, spit, spit, as long as I stayed. It was, perhaps, the poorest home I was ever in; but not so poor but there is money for tobacco. I know another poor man, about 60 years old. He has always been a faithful, hard-working man; but from boyhood he has drank, and used tobacco steadily. He is not a drunkard, but a steady drinker. He has quite a family; a nice wife; but the house, or shelter, they have lived in for 20 years is but little better than outdoors. He told me himself, that in very cold nights one of them had to sit up and keep putting in wood while the others slept, and that with their beds up close to the fire. I think they usually get enough to eat, but that is all. The rest goes to the saloon. I carefully figured up, the other day, from statements made by the man himself, and found that the money he had paid for tobacco and liquor, saved and kept at interest, would to-day *buy him my farm and home.* Now, it's a question with me how much charity we owe such men, and I should like your opinion, friend Root. *I* have saved my money, and bought a home; *they* have squandered theirs, and have got nothing. When they are sick and actually starving, why, then there is no question; but who wants to help them when half their earnings go for tobacco and liquor? But, how about their families? This reminds: I was traveling with a fine young man lately, whose father's name is known and honored throughout the United States. I missed him from the sleeping-car, in the evening, and, seeing him the next morning, asked him where he had been. He said he went to have a smoke, and fell asleep in the smoker, and didn't wake up till morning. I believed him, until I heard from the train hands that he had spent the night on the floor of the smoker, *drunk*. They wouldn't let him into the sleeper; but out of respect for his father they kept the matter quiet, and took care of him.

Take a walk with me through the streets of Chicago, St. Louis, or any of our large cities, and see the multitudes of children, hardly beyond the spanking age, who are smoking and spitting. Think of what they are probably coming to. It is appalling. It is well known, that tobacco is doubly injurious to the growing child. We ought to have a United States law, forbidding all minors using tobacco. When a man is full grown, and pays his own bills, let him use it, if he must, providing he does not marry. This is a little hard on some of the good married men who use the vile stuff, perhaps they may think; but I have got a dreadful thing to tell them. Not long since I was walking in the city with a celebrated physician. As we passed a house, surrounded with every evidence of wealth and refinement, he spoke:

"I have a patient in there, an idolized wife, who is dying, and beyond all help, and none of them know what is the matter with her, and still her husband has killed her."

"Why, doctor," says I, "what do you mean?"

"I mean just this," he says; "her husband is just literally steeped in tobacco, until the insensible perspiration from his body has become a deadly poison, and his wife has absorbed enough of this, and had, before I was called in, so that she will die."

"Have you told them?"

"No; what good? It would only add to their misery now."

"But, doctor, are you sure?"

"Yes; I have seen such things before. Some constitutions can bear the poison, and some can not. Why, just to give you an idea, I saw this experiment tried, among others, at an establishment where they treat patients for the cure of the tobacco habit. A man just brought in was washed as clean as soap and water could make him, and then some flies were allowed to alight on him. In five minutes, by the watch, they were dead. There was poison enough in the perspiration that came out of a man washed as clean as possible, to kill them. You can imagine what it would be, when he wasn't washed, perhaps, to spend hours each day in a warm bed with him."

This was all new to me, and I was completely dumbfounded.

I don't use tobacco, thank God, and never did; but if I had, that physician's statement would have stopped me as surely and quickly as a bullet would. Run any risk of killing my dear wife by my filthy habit? Not much! I would have slept in the stable; no, in the pig-pen; no, outdoors under a tree, far from every live animal, until the poison was all out of my system. T. B. TERRY.

Hudson, O.

Why, old friend, you have got away ahead of the whole of us in regard to the tobacco reform. I was prepared to believe that people sometimes kill themselves by its use, but I did not dream of such a thing as their killing others who are obliged to be near them. Your remarks explain something, however, that I did not understand before. Whenever I am obliged, even for only a little time, to remain in a room or car filled with tobacco smoke, it sickens and crazes me, and sometimes I have noticed that it takes two or three days to recover entirely from the effects of the poison. May be I could get accustomed to it in time, as I have become accustomed to the poison of the bee-sting; but I believe I would rather remain as I am in this respect.

A few days since, myself and two other bee-friends were obliged to wait for a train at Ann Arbor. To while away the time, we had a friendly dish of oysters, in a clean-looking restaurant. While paying our bills a troop of juveniles entered. Every one of them had a cigarette in his mouth, even away down to the small boy with short trowsers. Why, he was not very much bigger than Huber; and the sight of this boy, inhaling the fumes of tobacco, the blood in his youthful veins being stimulated by the vile narcotic, almost made me shudder. Dr. Mason suggested to the proprietor that boys ought not to be allowed to smoke in such a place.

"Why," replied one of the small ones, "he sells us the cigarettes hisself."

That was a clincher. So long as the proprietor sold cigarettes, the boys had a right to smoke them on his premises. It is positively appalling to see these little ones rivet the chains of a vile habit while they are too young to discriminate. I wish I could see these boys' mothers.

Friend Terry, I, too, thank God that you do not use tobacco; for, to tell the truth, I did not know, until just now, but of course I might have known, that men like yourself, Prof. Cook, and, I think I may say, the entire corps of contributors of GLEANINGS, without many exceptions, would not, on general principles, use tobacco, because they love their wives, as you put it (the *queens* of our homes, you know); they love their fellow-men, and they love their Maker. Now, I feel glad to think that we can join hands in this work, and that we can join in our daily prayers in pleading with the great Father for the boys of our land—yes, the juveniles, even if it is true that the grown-up ones are, many of them, past saving. By all means, let us have a U. S. law for the protection of minors.

SMOKER FUEL; MANAGEMENT OF SMOKERS, ETC.

DOES HEAT CURE DIARRHEA?

LAST winter, some time in February, if I remember correctly, there appeared marks of diarrhea in a few colonies in one of my cellars. The weather had been pretty cold, and fires had been rather low. I increased the temperature by better fires, and there were no further appearances of diarrhea. I do not conclude from this that heat is a sure cure for diarrhea, but I look upon it as a straw blowing in that direction. There are so many chances for mistake that I may be deceived in the whole affair.

SHAVINGS FOR SMOKER FUEL.

In GLEANINGS for Oct. 15, Ernest tells how he uses sawdust; and for such as have plenty of the proper material on hand I do not know of any thing better than to follow his instructions; for with my plan and my shavings, instead of his sawdust (for I can not get sawdust such as he uses) I am obliged to replenish my smoker oftener than he; but some, I think many, can not get his sawdust; and even if other sawdust would do just as well, there are some who do not have plenty of rotten wood. Let me tell you just how I use shavings; and for starting me in the use of them I would not begrudge many times the price of Mr. Heddon's book. In a convenient place in the apiary stands a box, of one or two bushels capacity, in which I put common planer shavings of pine. The box is covered with a tin hive-cover, so that it is thoroughly rain-proof. In this box is a small tin box containing matches, and a baking-powder can, to hold prepared rotten wood. Ernest suggests another baking-powder can to be used as a sort of scoop with which to fill shavings into the smoker. The rotten wood is prepared in this way: In a stone crock or other vessel I put something like a gallon of water and a pound of saltpeter. To this I add a little red aniline dye, not because it makes it any better, but so that I can tell at a glance whether the wood has been prepared or not. After the water has dissolved the saltpeter, I fill it with pieces of rotten wood, something like the size of a hickory-nut; let it soak perhaps two days, then take out and dry, and it is ready for use. If I am using Bingham's "Doctor" smoker, I put into the smoker enough shavings to fill it half an inch or an inch deep, then touch a match to a piece of saltpeter wood, drop it into the smoker, and fill the smoker nearly or quite full of shavings, pressing them down pretty hard. The saltpeter wood will be in no danger of going out while this is being done, even if the bellows is not worked. Instead of putting wet carpenter shavings on top, as Mr. Heddon directs, I find it usually more convenient to pick up a little bunch of green grass, and I find this answers the purpose. I have, however, had made a circular piece of tin, filled with ⅜-inch holes, and having a diameter about ¼ inch less than the diameter of the smoker. A piece of wire, fastened into the central part, serves as a handle, and this piece of tin being always on hand serves in place of wet shavings or grass. An improvement, perhaps, would be to fasten the circular piece of tin in the nozzle of the smoker.

I have made an entire success of using planer shavings in a Clark smoker. To light it I take a piece of saltpeter wood, light it, and put it in the smoker, either after putting in a few shavings, or after the smoker has been crammed full of shavings. Then I blow till it is well going. I find that it works just as well in the Clark as in the Bingham.

I like the Bingham better than the Clark, because it requires no cleaning of the tube, and is good, whether old or new. I like the Clark, if the tube would not fill up, better than the Bingham, because it costs less, and because it sends a stronger blast. A *new* Clark is about perfection.

LEGISLATION FOR BEE-KEEPERS.

A committee was appointed at the North-American Convention at Indianapolis, to inquire into the desirability and feasibility of obtaining such legislation as would secure bee-keepers a right to certain territory, without fear of intrusion from other parties. The convention by no means indorsed such legislation, for I think few of them had given the matter enough previous thought to be familiar with it, but they merely thought worth while to inquire into the matter. If bee-keepers will give their views through the bee-papers it will help the committee to make a more intelligent report at the next meeting. Please give us your reasons for and also against either the desirability or the feasibility of such legislation. C. C. MILLER.

Marengo, Ill., Dec. 1, 1886.

P. S.—Since writing the above, GLEANINGS for Dec. 1 has come to hand, and I will say to the good friends Z. T. Hawk and A. F. Stauffer, that I will try to reply soon to their courteous remarks and queries. I will just say to friend Hawk, at the risk of lowering his estimation of my intelligence, that I am not joking, but in dead earnest; and although not certain, I *think* I am right. At any rate it will do no harm for us to talk it over in a good-natured way, and I will try hard to keep down my temper.

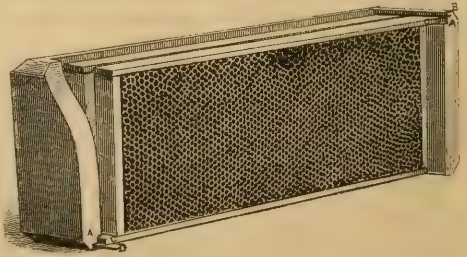
M.

Friend M., I think there is no question but that heat will prove a perfect cure for most forms of diarrhea, providing it be administered just right. You know all of our old troubles of spring dwindling gave way to the influence of warm sunshiny weather, especially when it came accompanied with honey from the soft maples or from fruit-bloom.—I am glad to hear your good words for the Clark smoker. At the Michigan Convention we had some good-natured jokes in regard to our respective smokers, and some of them seemed a little surprised when I told them I never claimed that the Clark smoker was the *best* smoker in every respect. In fact, I always feel a little modesty in claiming that any thing made by myself is better than anybody else can make. Even if it were a fact, I don't believe I should want to say it. If the Clark sends a stronger blast than the Bingham, even when new, I think that is a pretty good recommend for it. We are working hard on the problem of making one so the blast-tube will not fill up.—You may be right in regard to the matter of legislation, but I fear there will be a heap of objections before we can bring it to pass. I for one should be very glad indeed if I could purchase the privilege of keeping all the bees that are kept, inside of a certain district, without being obliged to purchase the entire real estate of that district. If it can be done, it will certainly be a great thing for bee-men, and, in real truth, it will not harm the occupants of said district, or inconvenience them to an amount great enough to be estimated. Perhaps we might buy the privilege of the land-owners, in some localities. Go ahead, friend M. We shall be glad to hear what you can suggest in the matter.

KRETCHMER'S INVERTIBLE FRAME AND HIVE.

AN INGENIOUS ARRANGEMENT.

THESE frames are separated from each other and from the case, and have all the lateral adjustments of the Langstroth frame. By referring to the illustration below it will be seen that only the right-hand end of the top-bar projects beyond the end-piece of the frame, resting on a rabbet, A, which is less than ¼ inch; while the left-hand end of the bottom-bar, C, projects likewise into a similar rabbet of the hive, resting on a strip of metal, D, inserted into a saw-kerf cut in the end of the hive.



KRETCHMER'S METHOD OF MAKING AN INVERTIBLE HIVE AND INVERTIBLE FRAME.

To remove the frame from the hive, we have only to lift the right-hand end a little in advance of the left-hand end. This movement disengages the lower left-hand end of the bottom-bar, and the frame, with comb and bees, can be removed or adjusted to any place in the hive as readily as an L. frame. To invert the comb, simply turn the frame end over end, and it is ready to be inserted into the hive in an inverted position, as top and bottom of the frame are alike.

If the condition of the combs is such as to admit inverting them all together, we slip a strip of metal like D (usually a ⅝-inch strip of hoop iron), into the saw-kerf B, over the ends of the frame-tops; and the entire case, with frames, combs, and bees, may be inverted, end over end; and when thus inverted, the case and frames, with their adjustments, are just the same as they appeared before inverting. In fact, both top and bottom of both hive and frames are alike; and, regardless which side of the case is up, any frame can be removed from the top as readily as an L. frame, by removing the metal strip D, which was below the bottom, now over the ends of the top-bar. A hole or two pierced into the metal strip, into which a nail, or the corner of the putty-knife, may be inserted, assists in removing said strip.

While these frames work well in a hive as deep as a Langstroth hive, we use them in our two-story alternating hive, the frames of which are only six inches deep. When of such depth they can readily be handled with one hand; although in a hive, practically arranged to alternate the upper with the lower story, the combs require very little handling. In fact, we don't handle one frame in this hive where we handle four in any other hive, to accomplish the same result.

A few weeks ago, while looking over my past records of wintering bees under various conditions and preparations, I found that I had sustained less loss of bees in the alternating hive than in any other, although wintered on the summer stand, which I attribute largely to their thorough central communication, the two cases of brood-combs being 12 inches deep, with a ¼-inch space through the center. Do not understand me as advocating *tall* hives. I have used hives with frames 14 inches deep, and sustained heavy losses, as tall hives necessarily are of small circumference, and the cold penetrates from all sides, and reaches the bees sooner than in a shallower hive.

E. KRETCHMER.

Coburg, Iowa, Dec., 1886.

Friend K., your plan is not new, so far as the frame is concerned. The idea, however, of slipping a piece of hoop iron over the frames, so the hive may be inverted, is, so far as I remember, original. The whole difficulty with such an arrangement is, that frames supported by opposite corners are not firm and substantial. If heavy with honey, the upper unsupported corner will sag over to one side or the other, and nothing will keep them in place except projecting wood, nail-heads, or something of that sort, and then we have frames at fixed distances. We give the illustration more to show to others that this field has been already worked over, than with the hope that it will ever be adopted. Of course, it would work very much better with a shallow frame, say five or six inches deep, than with the ordinary L. frame. A broad base would also help the frame to stand securely.

FRIEND DADANT IN REGARD TO THE SALE OF HONEY.

CAN IT EVER COMPETE WITH THE SUGAR-INDUSTRY?

FRIEND ROOT:—You will not be astonished if I come forward to take issue with friend Heddon on his article, page 882. He and I hardly ever agree on details, but we have never fallen out with one another, even if we have had pretty warm discussions in different papers.

Friend Heddon says honey will never become a staple. Are not syrups a staple? And is not honey better than syrup, and more healthful? Indeed, we have low prices; but how long will that last? By looking back to our accounts I find that, in 1880, only 6 years ago, we were selling honey, *at wholesale*, in 5-lb. cans, at 75 cts. per can, or 15 cts. per lb. In 1883, only 3 years ago, we sold 14,358 lbs. of honey (28 barrels) to Thurber, Whyland & Co., of New York, for $1435.80, or 10 cents per lb., delivered in New York city. This was mostly *fall honey*. At these wholesale prices, the honey was retailed at not less than 18 or 20 cents, and, of course, could not be expected to compete with syrups.

This year, for the first time, we are offering honey in cans, at 8 cts. wholesale, and 10 cts. retail; and it is selling well, although, to be sure, we have to *offer it*, and we would sell but little if we should sit down and say, "Honey is not a staple, never will be, and is only fit for sauce," which is the long and the short of Heddon's argument.

But can honey become a staple, and compete with syrup, so long as it is retailed at 10 cents, while the best granulated sugar is only 6½? Evidently not; and yet bee-keepers, owing to the new methods of production, are overstocked with it, and can not realize more than 4 or 5 cents on the large markets. Why? For the very reason that they send it to the large markets instead of trying to make it a staple by selling it at home, for a trifle more than they can get on the wholesale market.

But Mr. Heddon and others will say, "I am not a peddler, nor do I wish to be." Very well; but you will find plenty of men who will peddle your honey for one or two cents per pound, and make big wages. The reason why honey is not yet a staple, like syrups, is, that consumers don't know that it can be had so cheap. They may read Chicago or St. Louis quotations at 4 or 5 cents, but they either see no honey at all, or the little that they buy is sold to them at 12 to 15 cents or more. As Prof. McLain truly remarked, in a visit which he paid us a few days ago, "Not one-fifth of the children, the world over, know what honey tastes like." Perhaps children don't like honey!

How can we induce bee-keepers to push their home market? If they will not listen to reason, they will learn it by dear experience. After a few sales in the large cities, at 3 or 4 cents per lb., they will conclude to job it in their own neighborhood at 6 or 8 cents. Then the people will learn to prefer it to syrups, and, for some purposes, even to sugar.

I see by the commercial reports, that there are 12 grocers in Dowagiac. How many of them keep your honey, friend Heddon? Of our 9 grocers in Hamilton, 7 sell Dadant's honey, and the other two do not sell it, simply because we considered their trade too small to be worthy of attention.

Will it pay to raise honey at 5 cents per lb.? We might as well ask whether it pays to grow wheat at

60 to 65 cents, oats at 18 to 20 cents, or to raise and fatten hogs for 2 or 3 cents per lb. And bee-keepers are just as likely to quit bee-keeping because of low prices, as farmers are likely to quit farming, from the same cause.

Friend Heddon undoubtedly makes bee-keeping pay, for he follows our methods on extracted honey, so far as we know, and his crops are always large. Our crop this season is 24,000 lbs., and the prospect is that we shall get rid of it without having to crowd it on the large markets, in competition with that of others. C. P. DADANT.

Hamilton, Ill., Nov. 27, 1886.

Many thanks, friend Dadant, for coming forward at just this point, and supplementing my own ideas with the results of your large experience. If it were only the bee-keepers who are in great trouble because the receipts but little more than pay expenses, we might have cause for alarm. Not an hour ago, a neighbor, who is a farmer, made the remark that his stuff would not sell for enough to pay the wages of his hired help, let alone his own time and the interest of his money. Now, I hope he will not feel hurt because I suggest that his attention was given too much to other business to make farming pay. I am sure that a man who would give his whole attention to this very same farm, and go into it brain and muscle, would make it pay; and so it is with bees. Very likely, bee culture will not warrant one in keeping very much hired help, and neither will farming.

EFFECT OF ALTITUDE UPON BLOOM.

DOES THE INCREASE IN ALTITUDE HAVE ANY EFFECT UPON THE BLOOMING OF FLOWERS?

I WISH to give you some observations on the influence of altitude. Two or three times the question has been asked in GLEANINGS, if, with an increase of altitude, the blooming of flowers is not later, thus prolonging the honey-season. I know that this is the general idea, but there must be exceptions. I live about three miles to the east of the crest of the ridge between the Mississippi and Tennessee Rivers, which runs nearly north and south, and the slope in the direction of my residence has a fall of about 100 feet to the mile. Now, with this difference in distance and altitude, the crest has had, for the last twelve years, an average advantage in earliness of about two weeks, and the same in lateness of frost in the fall, thus prolonging the season nearly a month. I will further state, as I think it has some influence, that our prevailing winds are from the southwest and west.

JAPANESE CLOVER—*Lespedeza Striata*,

Is a plant that I wish to call the attention of bee-keepers to—not as a honey-producer, but as an enemy of honey-producing plants. The first mention that I have of it is that one Thumberg, a German, saw it growing in Japan, nearly one hundred years ago. It was first seen in the U. S. in the vicinity of Charleston, S. C., about the year 1849, and has since spread over several States. It reached this section about three years ago; and from what I have seen of it I can nearly indorse Mr. Pendleton, of Georgia, who said, "It has great powers of endurance, and will absolutely root out and destroy every other living plant in its wide-spread path." This particularly includes white clover. You will first see it along railways and highways, and then it spreads over all the intervening country. As yet, I know nothing that will stop it, so I suppose it will continue its devastating march northward. W. H. GREER.

Paris, Tenn., Nov. 22, 1886.

Friend G., if the altitude were on a high hill or mountain, I think you would have found the later blooming, as has been mentioned. It is well known, that elevated lands are not so liable to be affected by frosts. This is perhaps owing to the fact that the cold air flows by gravity into the valleys, leaving the warmer air on the hill-tops.—I think the Japanese clover has been mentioned before. Will our friends at the experimental colleges tell us if they have found it as friend G. states—a dangerous weed? Gray's Botany calls it a great benefit.

QUEENS' VOICES.

PIPING OF QUEENS NOT MADE BY THE WINGS.

NOTICING an article in GLEANINGS of Nov. 1, on the above subject, induces me to relate an incident that came under my observation one day last spring; to wit: It was Sunday, and my wife, desiring to get along with as little work as possible in her apiary that day, concluded to catch the queens as they came out, and provide places for the colonies by the time they got ready to settle. She caught a Carniolan queen and some half a dozen or more workers under a glass, and then transferred them to a wire cage, and brought them in the house for me to admire. She set the cage down on a table, and went out to attend to her bees while I was busy reading. Every once in a while I heard a way-off sound, as if from a locomotive in distress, and finally was astonished to discover that the noise was made by the imprisoned queen. She would run round in the cage, making frantic efforts to get out, and occasionally stop still and utter her plaintive, distressing call, which was a long "toot" followed by two or three short toots, thus: *t-o-o-t, toot, toot, toot.* The call was so loud that it could be distinctly heard across a large room. I am satisfied that the queen's wings contributed nothing toward the sound, as they appeared perfectly still when she did her piping; in fact, frantic as she was to get out of the cage, she would always stop perfectly *still* before making her call. J. F. HARNER.

Taylorville, Christian Co., Ill.

Friend H., the tooting you mention is quite a common thing with us here at the Home of the Honey-Bees. When we have a lot of queens piled up on our mailing-table, ready to go off, they very frequently get to calling; and when the room is still, say after working hours, I have often heard them call so plainly that their different notes could be heard distinctly in an adjoining room, some distance away. The matter was written up some years ago, under the title of "Queens' Voices," and you will find something about it in the A B C book. Since you mention it, I recall to mind that they usually stand still when they utter this note. It requires some effort of the muscular system, for we can plainly see her little body shake and quiver when she utters the loud calls. We should like to have Prof. Cook tell us if they have studied up this matter at the college.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from Nov. 15.

CHAPTER XXXI.

Godliness with contentment is gain.—I. TIM. 6:6.

Most people consider winter a dreary season. It has been much so to me; but I believe I am learning to enjoy whatever weather God sees fit to send us. If we look at the weather as a gift from God, there should be nothing dreary about any of it; and this way of looking at the weather, and all things which are entirely beyond our control, is, I believe, the contentment mentioned in the text at the head of this chapter. I have told you how much I love and enjoy sunshine; yet during this winter I have been taking real enjoyment in seeing the sun go further and further toward the south, until it rises only a little way up, and is now almost away over in the southern horizon, even at noontime. Our new greenhouse, which I enjoyed so much a year ago, is now completely shaded by the new factory until almost noon; but when the sun commences to come back again, as it will in a few days, I shall have an additional enjoyment in seeing it illuminate the greenhouse more and more each succeeding day. I have enjoyed more than ever before, I think, gathering our crops and getting every thing snug and in good shape for winter's frosts. We have secured an immense crop of cabbage. I figured up, at the time we put them away for winter, that we had enough to furnish the Medina people with 100 lbs. every day for a year. Somewhat to my surprise, however, we sold nearer 500 lbs. a day than 100, so our large crop is going off very rapidly. Just before putting them away we put the price down to one cent a pound, and this probably gave them quite a start. We have, however, at this date (Dec. 15), advanced the price to 1½ cts. per lb., and still they go off quite rapidly. We base our price a good deal on the city quotations.

HOW TO WINTER CABBAGES.

In our locality, cabbages keep nicely in the open air by standing them together with the heads downward on a piece of ground where water can not possibly stand, and then shovel dirt on the roots until they are nearly covered. It pays to have order and system, even in so simple a matter as putting away cabbages for winter. Ours were set in six or seven large beds. Between these beds is plenty of room to drive a team. The earthing-up is done gradually, so as not to cause them to rot before cold weather sets in. The location chosen should be on some soft mellow ground where plenty of earth can be easily shoveled from the alleys or roadways, to cover the vegetables. The act of removing the dirt in the roadways also makes water-courses. In gathering the cabbage we have stout men in the fields pulling them, while a stout team of horses with a stout sled drive them to the place where they are to be put away. On the next page, our artist has given a picture of the team in the act of drawing a load of cabbages.

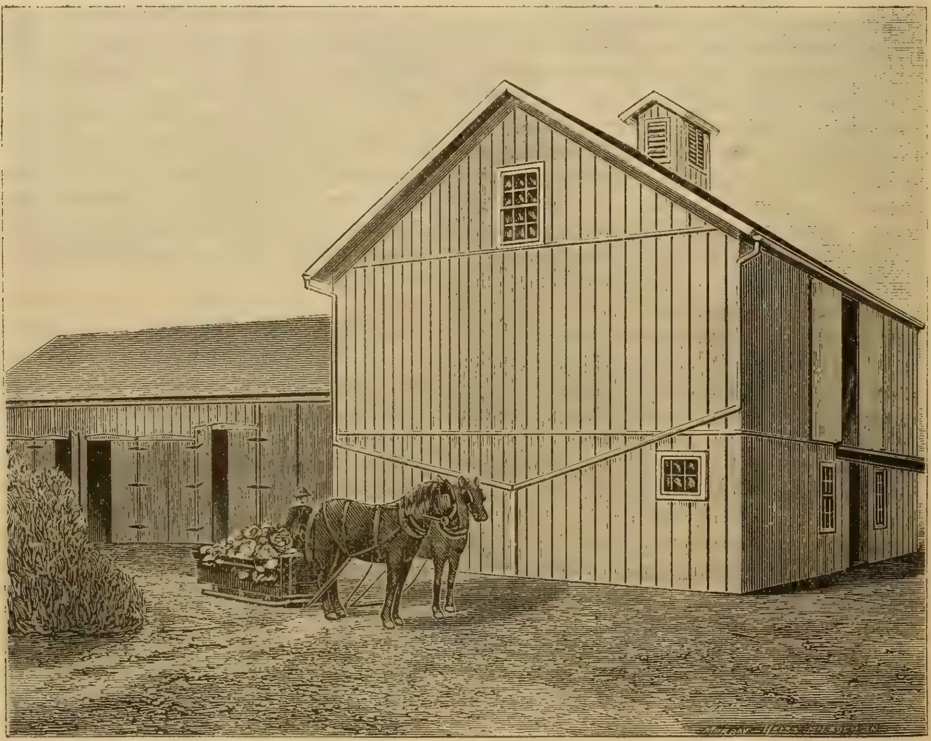
In the foreground is the new barn and toolhouse that I told you about last month. The bridge that leads from the embankment on to the upper floor is not very plainly shown. The tool-house has been so well described before, we need not take space to go over it again.

On the opposite page is a picture of the same buildings, taken from the cabbage-patch. The shed and poultry-house I told you about last month is now in full view. The glass sash, like a small lean-to greenhouse, is in the foreground. It answers the purpose admirably. Under the sash is plenty of dry earth for the fowls to wallow in, and bask in the rays of the sun. Over this earth I frequently give them a bed of forest-leaves, with grain scattered among the leaves. If you want to see fowls enjoy themselves just give them such accommodations. Their corner of the shed was, as I told you, done off with tarred building-paper and matched ceiling, and is, most of the time, too warm unless the sliding windows which you see are thrown open wide. The interior of the rest has been so fully described heretofore, that I hardly need go over it again.

When I was a boy I used to dislike to do chores more than almost any thing else. Feeding cattle, pigs, and chickens, seemed to me drudgery; but with the above-arranged conveniences, however, it is now one of the things I enjoy particularly. I like to go around at night, and see how thoroughly our plans for keeping out frost answer the purpose desired. I like to bank up earth or coarse manure over exposed portions, where the frost seems inclined to get in. I like to hear the pigs grunt *their* satisfaction with the arrangements made for their comfort. I like to see the chickens look at me inquiringly, as they utter a querulous note, as much as to say, "Do you really love us, and want to get acquainted with us?" I like to have the cows and horses put out their noses, as though they regarded me as a particular friend and not an enemy. While speaking about making arrangements to keep out frost, it occurs to me to mention that, where we have buildings without stone underpinning, or simply stone supports under the corners, we have been in the habit of cutting up old tinware, slipping one edge up under the battens to the out-buildings, and letting the other end come down into the ground. You can bank earth or manure up against this without any fear of rotting the woodwork. Around the pig-pens and poultry-house we have taken great pains to keep away water and dampness. To this end we have eave-spouting clear around these buildings, although they are not shown in both pictures; and along the edge of the weather-boarding a deep trench is made, the earth being used to bank up, as explained. The bottom of the trench is perhaps a yard away from the building, but it is so deep that the water is all kept entirely away from the interior. This keeps the earth on the inside of the poultry-house dry and dusty at all times. Now, I enjoy digging these ditches, and banking up the earth, especially where it is done *nicely*. No matter how hard it rains, no water can by any possibility back up into the interior of the building.

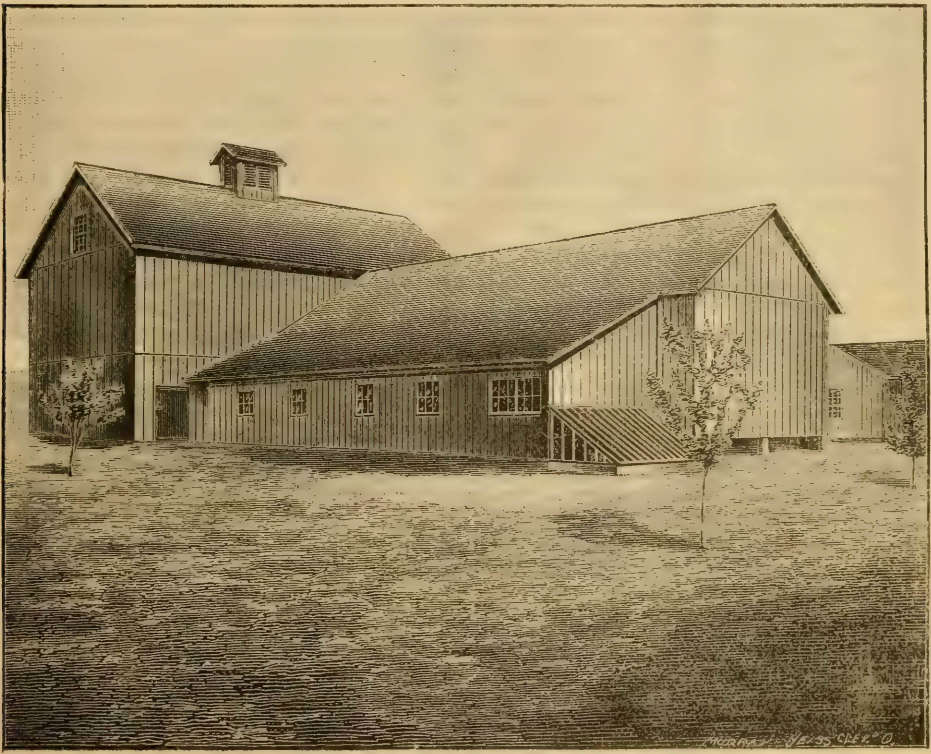
PREPARING CELERY FOR WINTER.

In speaking of banking up the earth around the outbuildings, as mentioned above, I am reminded of the matter of preserving celery for winter. As many of the friends have made inquiries in regard to keeping this vegetable safely, I will describe our plan a little in detail.



VIEW OF OUR NEW BARN AND TOOLHOUSE, WITH A LOAD OF CABBAGES IN THE FOREGROUND.

Where you have but few roots, of course the cellar is the usual way of saving them, and nothing more is necessary to keep them safely than a bottomless box or tub, the roots all being on the cellar bottom, or, if you prefer, in loose damp earth, directly on or in the cellar bottom. Where you have several tubs full, and wish to keep it some little length of time, the latter plan may be the best. I have seen a little bit of puddle, made right in the dirt of the cellar bottom, by digging a shallow excavation, and pouring in water. The roots of the celery are in this shallow puddle, while the tops are held close together and kept in the dark by the box or tub. These plans answer very well, providing your celery is soon to be used. If left too long it is apt to rot. Sometimes it will heat and spoil in a very short time, if you get too great a quantity massed up tight together, or if your cellar is very warm. Suppose, however, you are raising it by the acre, or in still larger quantities. In that case we adopt a plan similar to the one described for putting away cabbages for winter, only we are to remember that celery will not stand as much frost. Select a piece of dry, mellow ground. Thoroughly underdrained ground is by far the best. Of boards or plank, make a square inclosure large enough to hold your whole product when the roots are packed as close together as they will stand. Throw out the earth from the inside, and bank against the outside until the tops of the celery will hardly reach to the top edge of the boards or plank when the roots are in the earth. The location, besides being thoroughly drained, should be, if possible, protected from the prevailing winds. The rows of celery are taken out of the ground by plowing away the dirt with a one-horse plow, until the roots can be easily pulled by hand, without breaking or injuring them. If once plowing is not enough, plowing several times will do it. If the soil is very mellow, however, where the celery grows, it can often be taken up almost as quickly without any plowing. It will need two men, or a man and boy, to take up the roots rapidly. The man should have a tile spade or a potato-fork—we prefer the latter. By the aid of his foot he thrusts the fork deep enough beside the plant to pry it loose, roots and all. The boy then lifts the plant and shakes of as much off the dirt as will come off easily. The plants are laid in two rows, so as to be convenient for the team and sled, before described. When the sled is close beside the place prepared to put the plants, they are carried to the packer, who sets them up against one side of the excavation. To keep them from falling over, a board is placed a foot or fifteen inches from the side. This may be kept in place by



BARN AND TOOL-HOUSE, REAR VIEW, SHOWING MANURE-SHED, PIG-PEN, AND POULTRY-HOUSE, ETC.

means of stakes on the outside. The roots are then packed between the board and the wall, until reaching the corner. The operator will get along faster by having a low wooden box or stool to sit on. The boards to hold the plants in place may be the cheapest kind of culled lumber. When one row is finished, another board is put in, and then more plants, until the inclosure is filled. Nothing now is visible but the tops of the celery, and this is a little below the level of the sides of the pit. It is now covered with straw, swamp grass, or something of that nature, a little being put on at first, and more as the weather becomes cooler, about two feet being needed for a protection in the middle of winter. Over this straw, or poor hay, is placed a roof of culled boards, to carry off the water and to aid in keeping out frost. When the weather is *very* cold, close all openings with boards and straw and banks of earth, a place being left on one side to get in at, to get out the celery as needed. If you should find it covered with frost, and looking as if it were entirely frozen, don't be alarmed. It will thaw out and be as good as ever, if not frosted too severely. In fact, it is better to have a little frost, than to go to the other extreme, and keep it so warm as to rot. It rots very quickly, unless prevented by a low temperature. We now get 8 cents per pound for our celery; and although our people thought at first they never could like red or pink celery as well as the white, they now prefer it above the White Plume. Our best celery, however, owes its excellent qualities to its rapid growth on very rich ground, I think, more than to the fact that it is either white or red. The latter, however, has a nutty flavor.

In regard to the time of putting the celery and cabbage into their winter repositories, if they have not done growing I would let them stand as long as can be safely done without injury from frost. There is also much less liability of damage by rotting when they are left out until rather late, or until the weather is cool. In our locality, from the 1st to the 15th of November is about the time for putting them away. Sometimes we have freezes hard enough to do damage to them in the fore part of November, but not often; and, again, where the mild weather holds on until late, we may often safely wait until the last of November. One needs to watch for the right kind of a day, and then get out all hands and do it up quickly, to do the work to the best advantage.

BAROMETERS AND THERMOMETERS FOR FARMERS AND MARKET-GARDENERS.

It occurs to me here to mention that I have found a mercurial barometer a great help in this matter of studying the weather. Over and over again have I consulted the barometer in the morning before starting the men and teams to their work. For instance, we may have been waiting for a rain, in order to set out a lot of plants. When the barometer is falling, even though there is every indication of fair weather, all hands are set at work preparing the ground for the plants. Freshly prepared earth seems to answer much better for transplanting. Sometimes we get at the work of putting the plants out, before any rain has come at all; and then how nice it is to have a good shower just as the job is finished! I do not think the barometer has failed us once this season in this respect. At other times the appearances are very strong for a settled rainy day, but the barometer is steadily rising. At such a time I start the boys with the market-wagon, and the other team to cultivating, telling them there will not be rain enough to inconvenience them long. Sometimes the change of weather is slower in coming than I had expected, but it always comes, sooner or later. When I am in a hurry I can tell which way the barometer is tending, by a ltitle discovery of my own, but I have never seen it in print. It is this: Give the woodwork of the instrument a tap with your fingers, and the mercury will almost always start either up or down. This movement shows the tendency of the atmosphere. In an hour, give it another tap, and you can verify still further the way in which the weather is tending.

I have before spoken of the advantage of having a thermometer also; and of late we have been greatly pleased with a *self-registering* thermometer that tells just how cold or how warm it has been, even when you have not been near to look at it. This instrument sometimes helps me in this way: Some potatoes or squashes may be left exposed, and we are not yet ready to move them. I look at the thermometer, and find it stands 30° above zero. Now, I know this will not hurt them, because I have observed, a short time before, it went down during the night at one time as low as 25; and as the vegetables were uninjured, there is no immediate need of moving them now. We can not tell by our feelings how cold it is; but a very cheap *thermometer* tells us near enough for all practical purposes.

Now, one reason why I like to be up at half-past five in the morning, even in the winter time, is, that I may be able to meet every hand as he comes to work, in case the weather demands that he have different instructions from those given him the night before. The man who feeds and harnesses the horses, often needs, on account of a change in the weather, to put on the single harness instead of the double ones which were decided on the night before. By being on hand I can get every man started right, and in a way that will prevent conflict and annoyance. I have heard of people who could keep a number of men at work, and be away, letting each one manage himself; but I do not know how he can do it and pay expenses. He might employ a foreman, it is true; but where he can find a hundred men who will work very well under his supervision, he will not find one who could take charge, profitably, of even ten men.

COLD-FRAME PLANTS.

A year ago we succeeded splendidly in wintering plants for early cabbage, in a cold-frame, such as is illustrated in Chapter X. The labor of opening the ends is trifling compared with the usual way of removing the sash, or even sliding it back when more ventilation is needed. We have just finished a cold frame, and filled it with plants made on this principle, 22 x 28 feet. How I *do* love to see the plants thrive, right in the depth of winter! The sight of them is, to me, a constant reminder of the happy springtime soon to come. Yes, and there is another thing that I feel happy about. In two or three weeks more I shall commence starting celery-plants again; and how I do enjoy seeing our greenhouse and cold frames crowded to their uttermost, every inch of space being occupied with plants that are soon to take their place in the open ground. During the past season we succeeded in getting nice celery on the market in July. With the experience we have had, I believe we can do it this season even in June, and then we shall have celery almost, if not quite, all the year round. How I do love to raise celery and cabbage plants for sale! Although we thought we had a plenty beyond any demand that could possibly spring up, toward the last of the season we ran out of both celery and cabbage plants, and were obliged to purchase a good many thousands of each. Now, the purchased plants were none of them anywhere near equal to our own *transplanted* plants, and this year we think we can succeed in raising enough.

CHAPTER XXXII.

Let all things be done decently and in order.—I. COR. 14: 40.

I have several times referred to the matter of order and system; but I want to do it again in this chapter, especially in regard to laying out our ground and putting in the seeds. I prefer to speak of it now because it is winter time, and you have usually plenty of leisure to lay out your plans for another season. If you have not had experience, you may think it a simple thing to do the planning after the ground is fully prepared. My friend, when you are rushed and busy, during April, May, and June, you may be obliged to resort to one of two alternatives. One is to stop and do your planning while your men and teams are waiting for you. The other is, to let them go ahead without any plan, and take the consequences. One of the consequences will be, that you will have your stuff mixed up. For instance, you start to sow Stratagem peas, and the piece of ground you laid out for them will not hold all the seed. As you want it all used, the remainder is put in another piece of ground, perhaps some distance from the first. If you have not tried it you may be inclined to think this will make but little difference; but when your crops are all mixed up in this way you will find it a very great annoyance. It takes time to get ready to get at any piece of work—even a simple one like picking peas; and it takes time to move baskets, water-jugs, and other things, to another piece of ground to finish the job. Still worse, every little while somebody will pick one patch and forget about the other; whereas, if all your Stratagem peas had been in one spot, all the above troubles would have been saved. Again, you hurriedly bid the children go and pick the Stratagem peas. If there are *two* patches of the peas, the children will be sure to go to the wrong patch, even if you tell them distinctly. The consequence will be, probably, they will pick a lot that are not yet ready to pick. Last summer one of our very good girls picked about two bushels of *shell* beans, when she was sent to pick *string* beans. She was picking by the bushel, and, in her anxiety to make good wages, she did not notice the difference. It was all caused by the string beans being in *two* places instead of *one* place. Another time, a grown-up man with a family, and one whom you would think would know how to pick green corn, picked a lot of corn when hardly an ear was fit for use. If the corn had been all in one place, this would not have happened. I could go on enumerating mistakes and misunderstandings that have cost us time and money, all of which could have been avoided had our crops been divided off and placed in nice order, each different kind by itself. If you plant all your crops, and gather them all yourself, this in part might be avoided; but if your grounds are mixed up, a little bit here and a little bit there, you will find *yourself* skipping and forgetting something that ought to have been gathered before it got too old. During the past season we had cucumbers in five different places on our grounds, and we have scarcely a man or boy who would go over the whole of them without forgetting or skipping one patch or another until the cucumbers were too old to sell. The same with summer squashes.

How shall we manage to sow all the seed, and yet have it just fill the allotted space of ground, and have each crop all in one place? There are several things to be considered in order to accomplish this. One reason why we had cucumbers in so many places was because we put them in where some crop failed. How shall we manage so as to have no failures? Can it be done? I think it can. Have good seed that you have tested in the house, or in a hot-bed or greenhouse; or, better still, in the open ground, *the year before*. This latter plan will not apply to a few kinds of vegetables, but it will to the greater part of them. Seed that gave you a nice crop and a nice stand in 1886 will, almost without exception, give you also a nice crop in 1887. The few exceptions are, parsnips, onions, and leeks. Peter Henderson says he would just as soon have every thing else two years old, and no more, as to have seeds just gathered. Another advantage of using seeds that have given excellent satisfaction the year before is, that there is no mistake or misunderstanding about having the exact thing you want; for I tell you it is a terrible loss to find, after your crop is ready to harvest, that it is not what you meant to have it.

The matter of using the same seed for two successive seasons also helps us in having just so much ground for the crop, and having it all in one place. You see, you can lay out your ground in the winter, on paper, then sow enough seed to fill the allotted space, and put the rest away until next season; that is, when your seed is fresh. There is another advantage here: You have whole rows, and no pieces of a row. Sometimes you fuss more with a piece of a row, or injure the plants of half of it in cultivating, than the row is worth. By having *all* of each crop in one place we are also enabled to have long rows, thus facilitating the matter of cultivation. See Chapter XVI. You are also under the necessity of having but one label; whereas, if you had two patches you would have to have two labels. You may regard this as a small matter; but there are few things in raising crops that have made us more trouble than the matter of labeling. We have over and over again resolved that, no matter how hurried we were, every crop should be plainly labeled at the time it was planted. But year after year we come face to face with the sad fact that some crop we either want or don't want has no label on it; therefore we have no means of securing exactly the same another season, or of avoiding the same another season. As an illustration: We planted a patch of Hubbard squashes. I got a little impatient of some delays at the time it was put in, and suggested that there was no need of a label, because everybody knew Hubbard squashes as soon as they began to fruit. So the squash-patch did not have any label. Now, does it not really seem reasonable there was no need of any label on Hubbard squashes? In two or three weeks it was evident that the seed was old or poor, for the plants did not come up, even though the weather and soil were favorable. Then the question arose, Did we buy this Hubbard squash-seed of Henderson, Landreth, or of Gregory? The package containing the seed was thrown away—no one could tell. But I suggested that some other squashes be planted at one side of the hills, that would mature in a shorter time than the Hubbards. By putting them to one side we gave the Hubbards a chance to come up if they wanted to. If they didn't, the others could have the ground. *No labels were put on the last seed*; and when they began to be fit for use, they were something we had never seen before, and we did not know whether they were to be used as summer squashes, fall, or winter. Finally we tried selling some of them; but none of our customers liked them. We waited till fall, and tried them again, but with the same result, and we have a lot of them now that nobody wants. We are quite sure we don't want any more such; but as we don't know where we got the seed, how are we to be certain we shall not unintentionally plant the same thing another year? A few days ago I saw a *picture* of the squash we never want to see again, in one of Landreth's catalogues. It is what he calls his "White Turban," and it may answer a very good purpose on *their soil*, but we never want any more White Turban here, even if they *will* keep twelve months, as he says. Of course, it is one of the "novelties." Now a *most important* point is, it was put in our price list of seeds in 1886, because *Landreth* recommended it, and we would not have it in another season for any consideration. So much for the value of a simple label.

After we have decided that every kind of seed sown must have a good plain label, the question comes up, Where shall we put the label? Some of the friends might say, "Make a diagram of your grounds, in a book, and mark the articles so as to correspond with the diagram." This might do very well, but I do not know where we could put the book to keep it from getting lost, carried away, or mislaid. If we are to write on a stake, where shall we put the stake? Again, what shall we write with so the rains and sunshine won't obliterate it? I have thought a good many times I had found a pencil or a kind of ink that would write on a smooth stick, so the sun and rain would not fade it. The writing is all faded, however, sooner or later, and one of the results of such fading was, that early cabbages were sold to some of our customers when they wanted late ones. Several of my good friends purchased tomato-plants at "A. I. Root's establishment," so as to get something that was *absolutely reliable;* and instead of getting fine large smooth tomatoes they got—what do you think?—their garden-patch filled up with great nice vines that bore *pear-shaped* tomatoes for pickling, and nothing else. I am afraid that even their broad charity for a particular friend was a little lacking this time. I told the boys on the wagon to supply them with as many tomatoes as the plants would probably have borne, and take the pear-shaped tomatoes off their hands, and sell them, if they could, at some price. This was a great deal of expense and trouble and bother, and it all happened just because a little stake with two words on was lacking; namely, "*Pear-shaped.*"

Perhaps you begin to surmise, by this time, that I have some patent-right stake and label to sell. Not quite that, but I have found a plan that pleases me very well, and I think it will please you if you follow it to the letter. First get some stakes like the one pictured below. Let them be about a foot long, and made of inch boards, so as to be two inches wide at the large end, and slanting to a sharp point at the other.*

I would have them made of pine, because pine is slow to rot.

STAKE FOR LABELING PLANTS AND VEGETABLES.

The reason why I recommend putting in so much timber is, that we have been so much annoyed by small stakes being broken off by walking over them, or by the horse or cultivator. Stakes made like the cut above, if kicked, or caught by the cultivator, will pull out, and may be put back in the ground again, but they can not well be broken. How shall we mark the stake? Have some small-sized tacks in one of your vest pockets (tinned tacks are preferred), and with your finger and thumb-nail tack the label on to the stick—I mean the label on the package of seeds. If you buy a packet of corn or peas from any of the prominent seedsmen, you will find a printed label on the inside of the bag. Tack this label around the stake, folding the paper where the tacks go through, to make it thicker under the heads. Peter Henderson uses the best and stoutest paper for his seed-bags, of any firm I have dealt with. These labels will stand on the stakes over winter, and be just as plain in the spring as they were the fall before. Not only does this label tell the *kind* of vegetable, but it tells *of whom* the seeds were purchased. When we have a crop of turnips that pleases us, it is quite a gratification to us to see the name of Peter Henderson in large black letters, so plain that you can read it from almost any part of the turnip-patch. Where shall we put this stake with its stout paper label securely fastened to it with the tinned tacks? Now, you may think this is a simple question, but it is a matter of no small moment, I tell you. Suppose you have half a dozen different kinds of strawberries in one row, to be tested. Where will you put the stake? It can not be in the middle of a dozen plants, because the stake ought to tell where one kind ends and another commences. If, however, it is placed between two varieties, should it describe the variety in front of the label, or back of it? Mr. Seth A. Bushnell, who has spent almost a lifetime among plants and fruits, originated, I believe, the plan we follow, and he tells me that the great firm of Storrs & Harrison, of Painesville, O., adopt the same plan. It is simply this: Put down your stake before you commence setting out your strawberry-plants. Let the label face you as you look at the stake, and let the plants be set behind the stake. When you have set all of that kind, push another stake in the ground, with the label facing you as before, and set the plants back of the stake as before. I may say, right here, that the stake illustrated above can be stamped into almost any good ground with the heel of the boot, deep enough to be secure. Now, then, to our stakes and labels. When you get to the end of the row, turn right about and come up on the next row, setting the stakes before you as before, *with the plants the label describes always back of the stake.* Just keep doing this, and you will have no trouble, and there will be no confusion. If, however, you get up some plan of your own which you think is simpler, you will eventually run into trouble. I have tried it a good deal. These stakes and labels will even answer for potatoes. In hilling them up, if you should cover your labels and stakes with dirt, they can be plainly read by washing or rubbing the dirt off; but any kind of pencil or ink marks would be gone under the influence of dirt and water.

---

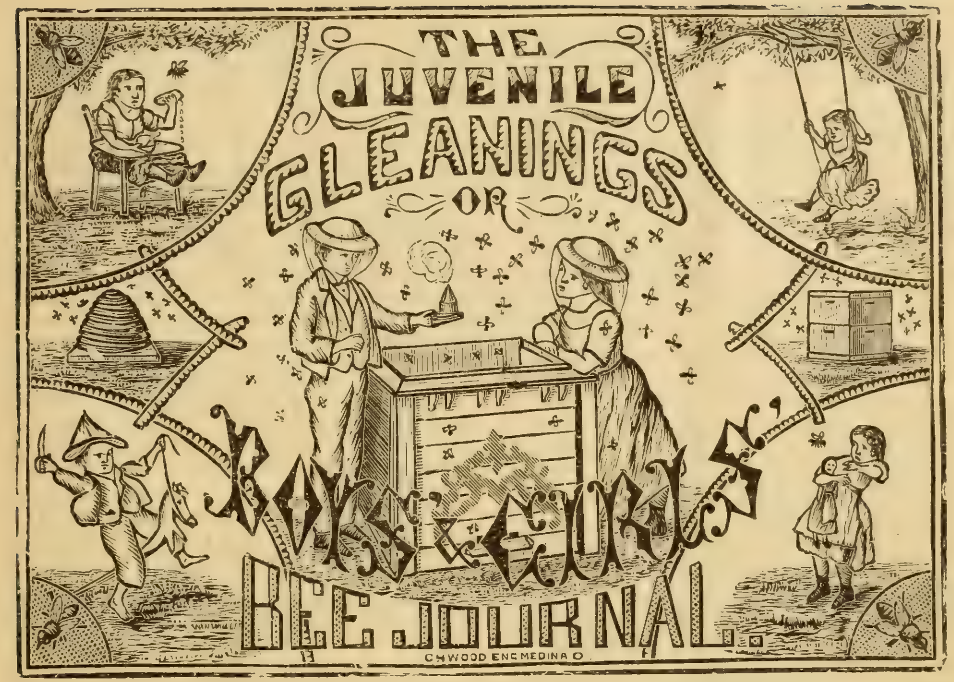
*They can be cut out with a circular saw, for 25 cts. per hundred, and probably even less stsll by the thousand.

HOW TO AVOID VACANCIES.

If one hill is missing, and other hills have more plants than are needed, choose just the right time after a rain, and transplant to fill up; but don't plant some other crop if you can avoid it. During the last season we planted white beans where our sweet corn failed. It was a bother to uncover the beans when covered by the cultivator, and it was a still harder one to gather the crop. Two very good boys went over the corn-field *twice* in order to get all the beans. But there are white beans now, dotting the ground, that have dropped out of the dried-up split pods. Had the beans been all in a patch by themselves, the boys would have gathered every pod; but scattered among the corn-stubble, they could not see them, and I don't know that I ever found a boy who could. All these things should be taken into consideration when planning our work. Make it so plain and simple that you can give orders to the different hands, almost without the possibility of a mistake or misunderstanding. Try in every possible way to avoid having things so mixed up that an old experienced *man* must be employed, in place of a comparatively cheap *boy* who will do almost as well if his work be so arranged as to make it pleasant and easy for the little fellow.

By doing every thing decently and in order, we make work pleasant and easy; but where we go ahead without system, or regard for consequences, the way is open for misunderstandings and fault-finding, and disputes in regard to whose fault it was that some accident happened. I expect, of course, you will raise your own seeds to some extent as soon as you can. How shall they be put away and labeled? In the outset, I would decide upon some special room, or part of a room, to be kept for seeds. Have it labeled "Seed-Room" so there may be no misunderstanding in regard to the locality, when you send even a child there for something. Then I would have the seed-room divided off into apartments, pigeon-holes, or something of that sort, for each separate kind of seed that you decide to handle. For peas, beans, and corn, and perhaps some other bulky seeds, you will need a sort of bin rather than a pigeon-hole. Over each of these bins, have, in plain large letters, "Peas," "Beans," "Corn," etc. When this is done each bin needs to be subdivided. If you are going to have four kinds of corn, and you can not well get along with a less number, have these subdivisions plainly labeled something as follows: Early Sweet Corn, Late Sweet Corn, Field Corn, and Pop Corn. Decide in this same way how many kinds of peas you care to handle, and have the pea-bin subdivided in the same way. I think my choice of peas, after our experience during the past season, would be something like this: Extra Early Peas, American Wonder, Stratagem, and Yorkshire Hero.

To be continued Jan. 15, 1887.



He that is faithful in that which is least, is faithful also in much.—LUKE 16:10.

MYSELF AND MY NEIGHBORS.

> Whosoever shall confess me before men, him will I confess also before my Father which is in heaven. —MATT. 10:32.

IN coming home from the Michigan State Convention, on account of the extreme cold weather the trains got behind; and on striking our own Medina road, I found that our train had been gone about twenty minutes. Under such circumstances, people usually decide to wait all day at Elyria, for the evening train. I made up my mind, however, that I was going to get home before night, by hook or by crook. The station agent said there was no coal-train nor freight that I could go on. Now, one who gives up easily might have thought that *that* settled the question; but I replied that I knew there was a coal-train some time during the afternoon. He admitted it, but replied they did not stop at Medina.

"But, my friend, they can surely be prevailed upon to slack up so I can jump off somewhere in the vicinity of Medina."

He replied, that they were often desired to do that very thing, but had strict orders not to do it. Now, a good many would have said that I was shut up on that score. Not so, however. I had begun to get a little acquainted by this time. You remember what I have been saying to you about getting acquainted with people, and the advantages it gives. When we had got into conversation so he did not regard me as one of that class of people who keep continually bothering station agents with useless questions, he suggested that I might see the superintendent of the local freight, and that *he* could, if he chose, give me a line to the conductor to slack up, as requested. He further remarked, that the superintendent would be at the depot in a short time. I told the superintendent who I was, and how important it was that I should be at my place of business, and he quite good naturedly gave me the written order I so much wished.

Now, friends, when we succeed in getting something we want from a neighbor, are we always careful to express our gratitude? I thanked the superintendent, and told him that, when it should be in my power to do him or his road a favor, to bear in mind that it would afford me pleasure to return the favor just granted. Then I went to the young man who is agent, and thanked him for so very kindly taking the trouble to help me get home. By this time I felt pleasant toward almost everybody. While waiting for the train, a couple of hack-drivers came in and sat down by the stove. A couple of loungers made the company large enough so they could tell stories. The stories were principally in regard to the ability with which different personages in Elyria could drink beer and whisky, and still stand up and walk around. A young lady came in to wait for a train. The station is a very small one, at the crossing of the two roads. There was only one waiting-room for both ladies and gentlemen. Now, these boys did not smoke in the lady's presence, but they told stories that were pretty nearly as offensive to good taste as tobacco smoke; and they seemed to think, that, because the lady smiled, it gave them permission to go on. Perhaps you may ask why I did not use my influence, or what skill I possess under such circumstances, to get the boys on to some other topic. Well, my friends, I studied hard, and prayed hard, but I did not see any opening for interruption, without having them think I was a sort of crank, or eccentric personage, who wanted to boast of his own goodness and Christianity. Even though this class of boys are coarse and low-lived in their ways and talks, they are keen enough as a rule, and bright enough, to see the consistency of things, and can read a man pretty thoroughly. By the time the train came I had not scraped up grace enough to say any thing *at all* for the *Master*. I do not mean that I did just right, however, for my conscience upbraided me for not being a more faithful witness. I hardly need tell you, that, as a rule, the brakesmen, and the men who are employed to load and unload freight, are a rough, drinking, and swearing class, and I fully expected to find such for my companions in the caboose car. But I decided that I would have a little more courage, and at least make an effort to win these men just a little during my 25-mile trip in the caboose car. The car was divided into two apartments by a sort of partition in the middle. Imagine my surprise to see, hanging over the doorway between the two apartments, a little frame in which was worked, in perforated paper, the words, "In God We Trust." As a rule, these caboose cars are embellished with pictures that the railroad men manage to pick up from illustrated newspapers, or the literature of the day, and I had made up my mind that the prints that adorned these walls were probably, many of them at least, questionable in their moral tendencies. Imagine my surprise to find they were not only beautiful, but chaste and pure, every one of them; and many of them had beautiful appropriate texts just under them. The occupants of the caboose car were out in the severe cold weather, moving the cars from one track to another, so I was alone for quite a time. When they had got by the station, and rested enough so they felt like talking, I began to get acquainted. Finally I motioned toward the motto, and commenced something as follows:

"My friend, is it true that you are sailing under these colors?"

He replied, modestly, "Mr. Root, I hope it is true that I am trying to live according to that text."

"Then you are a professor of religion, are you not?"

"Yes, sir, I have been for several years a member of the Disciple Church at Lorain."

"And you manage to hang to it, even if you *are* a railroad man?"

I smiled as I caught his eye when I made the remark. He nodded, as he replied, with a smile; and then I mentioned that I had been pained to notice the swearing and intemperance that were so often connected with his line of business. He replied, "I know just how that is, Mr. Root; but nobody has ever sworn at me since I became a Christian, and I thank God that I have never sworn at anybody else."

One of his boys, who sat near me, looked up from a newspaper he was reading, and smiled in a way that seemed to say that he, too, felt proud of the example this train was setting for others on that road. We had quite a long talk. This man not only knew Fred, whom my older readers remember, but he was on the train with him at the time of Fred's death. He and Fred used to attend the meetings at Lorain, without doubt, for several told me, shortly before his sudden death, that they had been having excellent revival meetings there, and that he, with some other railroad hands, had been attending. From what this man said of Fred, I can readily imagine that Fred's influence might have had a great deal to do with what I have just been telling you, for my companion was not a Christian when Fred met his death. How often these things come up! Is it not really and wonderfully true, that bread cast upon the waters does come back after many days?

As we came up to the station I told my new friend how rejoiced I was to find that I could think that, hereafter, I had a neighbor over on one of the coal-trains that pass us daily; and not only a brother, but really and truly a brother in Christ Jesus, even though he belonged to one denomination and I another.

During our talk he mentioned to me that a station agent on a road at a town a little below Medina had started out, a few months ago, to follow the Savior. He made hard work of it, however, and after a few months he announced to the friend with whom I had been talking, that he did not see how it was possible for a *railroad* man to be a *Christian*, and so he gave it up. He did not give up being a railroad man, but he gave up trying to be a Christian, and pretty soon the company gave *him* up. So the *result* was, at least for the time being, that he was not a *railroad man* nor a *Christian* either. May God help the poor mistaken brother, wherever he may be now!

But whosoever shall deny me before men, him will I also deny before my Father which is in heaven.—Matt. 10:33.

ARTHUR'S BEES.

A Story for Boys.

BY MRS. CASTELLA WHITMAN.

Concluded.

I HAVE before stated, that this family took great pleasure in caring for bees in the past; but it really seemed as if they enjoyed it far more the present season; and if ever a plowboy welcomed the sound of the horn, which was the signal that the bees had swarmed, it was Arthur. Well do I remember one warm summer morning, after they had hived one swarm, as his father had again started to his work, that he said, "If any more come out, call 'whoopy.'" He had gone but a few rods when he heard "whoopy!" from the apiary. He could scarcely believe it real; but the issuing swarm soon convinced him, and the children enjoyed the joke very much.

Another quite eventful day was when five swarms came out in about an hour—two of them so near together that they united. The only thing that interrupted the enjoyment of that day was the mother's sick headache. I think you have already guessed that she was quite an important factor.

I can not pass this season by without relating one more incident. A certain hive, one of their best, had been watched very carefully for several days, as the bees had lain out of it, not only covering the front of the hive, but also the cap that covered the second story.

One day after dinner, while their teams were eating, Arthur, being left in charge, his father thought to call on a neighbor to see if they could get any seasoned lumber, as their own supply had become exhausted, and still no news from the hives they had ordered. The father had seemingly been gone but a short time, when the above-mentioned swarm came out. Arthur, with other members of the house, stood watching them, as they usually did, to see where they clustered; but, without any halt or warning whatever, they rose above the surrounding trees, and passed immediately over the house. The shade-trees in front somewhat retarded their progress, and caused the greater part of them to descend in order to pass under the branches. Here every possible effort was made to detain them, but to no avail. They had become so much enraged by this time that Arthur's mother was forced to retreat, while he nobly pursued them. She could not leave him thus to his fate, as it were, but soon followed on. Arthur nearly kept pace with them until they came to a thicket, which on ordinary occasions was thought impassable; but in his eagerness to follow them he said he did not even give it a thought. Soon they were in an old pasture, among scattered timber. Arthur here thought he had lost track of them, and paused for the first time. Glancing around (or, rather, above) he saw them flying about the top of a very tall tree, and soon concluded they were entering it, as only a few remained in sight. His mother, not venturing to take a bee-line, as her boy had done, went round and accidentally came across his father on his way home, so all three were soon on the spot. The tree, not being a valuable one, they received permission to cut it; and on measuring it they learned their bees had entered seventy-five feet from the ground.

Arthur and his father were obliged to spend nearly the whole afternoon in securing them; but at nightfall they had the pleasure of returning them to the apiary. This was their first experience with absconding swarms, and it was quite an experience too. Their new hives came in time to receive three small swarms. The day Arthur's father went after them to an adjoining town, Arthur took his first lesson in hiving a swarm. It was quite different from having father there, to take the responsibility. Just imagine, boys, all of you who may chance to read this, the scene on the barn floor, the afternoon these hives were brought home, for as yet they had no shop. All the male members of the household were there to lend a helping hand, the little boys from their play setting up sections, Arthur and his next younger brother from the field nailing frames together, and the father at the helm doing the more difficult part, such as nailing the hives together, putting metal corners on frames, etc. Even grandpa sat on the crate that contained the hives, watching the workmen, and it really seemed like a little factory.

Reader, I will pass on, before my story wearies you, and close the most happy and prosperous year they had yet enjoyed. Before opening another year's history I will merely say, that the road through life is as changeable as are our seasons. The long cold winter was again over. Arthur would inquire, as an occasional warm day passed, if any one had seen their bees flying; and, still later in the season, as these pleasant days grew more frequent, his anxiety increased in not seeing them out, neither answering to his accustomed tap on the hives. At last, resolved to know their destiny, the hives were opened. Imagine Arthur's surprise and grief when not a living bee could be found! This was the first and only property he ever possessed. They all had plenty of stores, and no disease seemed to have been among them, so the conclusion was that it must have been the long cold winter. Really, Arthur's father sustained the greater loss of the two, as he had been at considerable expense, feeling that he could not be at any more, under present circumstances. He kindly offered the hives to Arthur. Buoyant with hope, and the encouragement he had received from GLEANINGS, he soon sent an order for a queen and half a pound of bees. When the postal came, stating that they had arrived at the express office, Arthur was a mile from home in an opposite direction, at work with his father. His brother, being eager to carry the news, he was soon notified, and, receiving permission, he started on foot to get his coveted treasure. What a happy boy he was, as he started from the office, with bee-cage in hand, and was accosted by one and another, as, "Those are your bees, are they?" signifying that they had attracted much attention. As he neared home his steps grew slow, and the miles seemed to lengthen ; nor was it to be wondered at, as he had done nearly a day's work, and then walked about ten miles. The satisfaction of seeing his little swarm of bright Italians placed on frames in one of their new hives that had been left desolate a few months before, was sufficient recompense for all he had endured.

By watching them carefully through the summer, Arthur had as nice a colony in the fall as one could wish. But, dear reader you may rest assured that many precautions were taken to keep them through the winter. The A B C book was carefully studied, and many of the precepts in GLEANINGS were practiced.

Midwinter had now arrived, and what was Arthur's surprise when he read that the North-American Bee-Keepers' Convention met at the metropolis of his own State! What an eager expression was on his countenance, as the subject was referred to indirectly! One and another would ask if Arthur and his father thought of attending. Of course, they would be very anxious to; but, taking all things into consideration, whether it would be advisable or not was the question. Arthur's mother felt, that perhaps a golden opportunity might be lost, as, among the names of the announced speakers, were those in whom they had placed the utmost confidence—known only to them, however, by their writings. Then there was the inducement in the reduction of railroad fare and hotel-bills. All combined seemed to influence them to go, except the changeableness of the wintry weather. The decision was finally made in their favor, and willing hearts and hands soon made them ready.

A deep snow had fallen a few days previous, then a rainstorm coming on a short time before the eventful morning in which they were to start, left the roads in such a condition that they could not reach the station without being carried, at that early hour in the morning, as it was several miles distant. So Arthur's mother volunteered to act as driver. At two o'clock in the morning, Arthur, with lamp in hand, was arousing the family, and at three they were on their way to the station. They arrived in due time to attend the morning session of the convention; and to say that they enjoyed it would be but a meager expression. They met with many whose names were as familiar as household words, but their faces were as strangers.

Upon their return home they gave such an accurate description of what they saw and heard that the whole family seemed to have had the benefit of a part of it at least. The convention was the crowning enjoyment of Arthur's boyhood days; and should his success in life be even greater than a farmer-boy might anticipate, his mother will attribute it to his first swarm of bees, and the association and influence connected therewith.

I am happy to tell the readers of GLEANINGS that it was my good fortune to meet Arthur and his father and mother at the recent State Convention at Ypsilanti. I am glad the little story tells the dark side of bee culture as well as the bright. I am also glad to know that Arthur was not disheartened, even after his heavy losses. If he continues to attend conventions, and gather facts from the bee-journals, he will, without doubt, succeed. After one has successfully brought his bees through the winter once or twice, it seems to be a comparatively easy matter thereafter.

A GOOD REPORT FROM W. E. FLOWER.

THE ALLEY TRAP AND QUEEN-EXCLUDING HONEY-BOARDS.

I HAVE used half a dozen of Alley's queen-traps for two years, and they have never failed to catch the queen. I have also used half a dozen of your zinc honey-boards for the same length of time, and they have proved a grand success. With these two appliances I have no fear of swarms going to the woods, or queens getting into the sections. I don't want to puff you or Alley; but if you think it worth while I will give you a brief article describing how I use them to prevent absconding and after-swarming, and but little increase. I can and do go to church and Sunday-school every Sunday during the swarming season, and have not lost a swarm in the two years that I have used them. I don't suppose that my methods would suit either Heddon, Doolittle, or Hutchinson; but they might suit some one who, like myself, keep a few colonies, and who have to leave home to work in a factory all day, and have no time during working hours to be hunting queens, climbing trees, etc., after swarms.

Ashbourne, Pa., Nov. 6, 1886. W. E. FLOWER.

Friend F., we are very glad indeed to hear from any one who has found these helps a positive success.

JUVENILE·DEPARTMENT
F.A.W.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from $1.00 to $1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

CONDUCTED BY ERNEST R. ROOT.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

JIMMY'S SUCCESS.

AFTER the events recorded in the last issue, Jimmy went to bed, but not until he had washed the mud from his face.

"Well," he thought, as he lay in bed, "if the mud didn't do my face no good, it made pa laugh, and I guess he won't make me give up my bees after all."

His mind wandered from one thing to another. He thought what Sam would say when he heard what happened; then he wondered whether his three other colonies had enough feed. He well knew that the robbed colony was in no condition to winter.

"By cracky!" he said, almost aloud, "Mr. Green told me to open the entrance of that hive which was being robbed to-day, and I forgot it. I must do it to-night. But ma won't let me fix them up to-night."

A bright thought entered Jimmy's mind. He crawled out of bed, raised the window very carefully, and stepped out into the night air with only his night-gown on. It was chilly; "but," he thought, "it won't take me but a minute."

In a moment more the entrance was opened, and he hurried back to his window.

"Cracky!" said Jimmy, as he tried to raise it, "I forgot about that ketch when I left, and how am I to get in again?"

There was only one alternative, and that was to knock at the door. It was so chilly that Jimmy did not hesitate long, attired as he was, and gave a knock. In response, his father came to the door.

"Why, how came you there? I thought you went to bed over an hour ago," said he greatly surprised.

"Yes, I did go to bed," explained Jimmy;

"but, but, Mr. Green told me to open the entrance of one of those hives 'cause they'd die if left long, and I happen ter think of it when I got ter bed, an' I thought I'd go out the window an' not wake you and ma up. I forgot about the window-ketch, and when I came back I couldn't raise it, so I come round by the door."

Jimmy had not told the straight truth. He went out by the window because he feared his mother wouldn't let him go if he asked her permission. Jimmy would not be guilty of a lie, but lately he had got into the habit of "stretching the truth."

Jimmy had hardly finished his explanation when his mother, from the adjoining room, called out—

"What's that child been up to now, I'd like to know? Outdoors with nothin' but his night-gown on!"

Without waiting for a reply, Jimmy scampered off to his room and into bed, leaving his father to make matters right.

The next morning after breakfast, Jimmy thought he would take a look at the colony, the entrance of which he opened the night before. Most of the bees were in the bottom of the hive, and what were not dead were wet, or, as Jimmy expressed it, looked as if they had "been sweatin'."

Besides all this, the robbers were again at work; but on this occasion Jimmy had taken precaution to provide himself with a veil, which Mr. Green had given him along with the old hives. Unable to account for this peculiar condition of the bees, Jimmy scampered over to Mr. Green's.

"Hello, Jim!" said Sam, smiling, whom he met first. "You got stung, did you?"

"Where's yer pa?" said the other, without making any reply.

"Down in the lot by the creek, husking corn. Why? what do you want?"

"Oh! my bees have got to actin' up."

So saying, Jimmy started toward the creek in pursuit of Mr. Green, followed by his companion. When they had reached Sam's father, Jimmy then explained the condition he found his bees in in the morning. When he had concluded, Mr. Green then replied, "I suspect you forgot, and left the bees too long after I closed the entrance, or they would not have been in that condition. From your explanation, I judge the bees had smothered. How long was it before you closed the entrance?"

"Well," said Jimmy, willing to own up, "I forgot it, an' just before I went ter sleep I happened ter think of it, an' I got up and opened the entrance."

"What time was that, should you think?" asked Mr. Geeen.

"Oh! 'bout ten; or half-past."

"Well," said Sam's father, "that would make eleven hours; and the hive, when I closed it, was full of robbers. Besides that, the sun shone pretty hot all the afternoon; no wonder you found them as you did."

"What'll I do now?" said Jimmy.

"You say you opened the entrance this morning, and that the robbers had already commenced. I should advise you to take out the combs, if they have not melted down; brush off what bees may be on them, and carry them to some place where no robbers can get at them. Next pick up the hive and all, and dump your 'sweaty bees,' as you call them, into your other three hives—about an equal portion in each. You must do your work quickly, and you must not run if a couple of bees sting you."

"All right," said Jimmy, starting off on a run.

"One more thing," called out his teacher; "get your smoker going good, and put on your veil."

"I will," said Jimmy, and the boys were soon out of hearing.

Jimmy followed directions exactly, and, four or five hours after, reported that all was quiet; but he said his other three hives were "carrying out lots of dead bees—yes, lots of 'em."

Mr. Green told him that these were only the dead bees he had dumped in from the robbed colony. About a week later an examination into the three remaining colonies showed that the bees had done their work well, yet you could easily see that those bees which were so nearly dead were shiny black fellows, without any fuzz on their backs.

Better than all, Jimmy's father and mother had both agreed that he might keep his bees, although for some time his step-mother persisted that he should not keep them.

For the present we will leave Jimmy and his bees, and listen to what other boys and girls have to say for themselves.

CORNCOBS FOR WINTER PASSAGEWAYS.

My pa fills the tops of his hives with corncobs, for the steam to gather on, and when it gets very cold he wraps the hives with old carpet. He winters his bees out of doors. EMMA S. MYERS.

Lafontaine, Ind., Nov. 27, 1886.

A LITTLE ORPHAN BOY'S REPORT.

I am a little orphan boy. My father died six years ago, and my mother died last September. I am now staying with my uncle, and help my cousins, Gabe and Andrew, take care of their bees. They have 75 stands, which they are going to winter in the cellar. The three years they have kept bees they have lost 5 colonies in wintering. Last summer they got 1400 lbs. of comb and 300 of extracted honey from clover and raspberry. Basswood was an entire failure.

HENRY ANDERSON, age 12.

Marshville, Mich., Nov. 18, 1886.

FROM FAR-OFF NEW ZEALAND.

We are having a very wet winter, and my mamma has to feed our bees. My papa is afraid of them, so she has to manage them by herself. Sometimes our neighbor, Mr. McPherson, comes and helps her. He is very kind. He can manage bees very well. He has over twenty Langstroth hives, and he has some common boxes. Some people say, that when a bee stings any one it dies. If so, do you know how long it lives after it has lost its sting? Mamma bought three colonies of bees, and packed them herself, to come a long journey. They traveled for four miles on a dray, on a rough road, and then they were in the train for more than an hour; then in a spring cart for eleven miles, and not one of them got out. JESSIE HYDE, age 11.

Otau, N. Z., Sept., 1886.

A bee which has lost his sting, if confined in a queen-cage, will not live much over 24 hours; if allowed his liberty he will live from a week to two weeks. I would refer you to this department in back numbers of the past year for a full account of experiments upon this point.

“EGCATION.”

The following is from a little friend who evidently wrote hurriedly. As it is quite original, we insert it just as she has sent it to us. If you are careful I think you can make it out.

I seat myself to write you a few lines I went To sunday school nearly all Sumer I like to go to Meeting the meeting house is about 2 miles and a half off, Our school is a going to comenst a munday I expect To go to all winter I never went to school very much Buch but I am glad I hav As much egcation as I have Papa has nobees bu he wants To get some so I can no think of no more at presant ZYLPHA A.

“Egcation” surely is a nice thing, don't you think?

SO SICK FROM THE STINGING THAT HE COULDN'T SEE.

My papa has 2 stands of bees. He had 3 last winter, but one of them froze. Last summer, when they swarmed, they went across the railroad and settled on a willow-tree. Papa told a neighbor to jar the limb, and he hit it with the hatchet and made them mad. They stung papa, and made him so sick that he couldn't see. This summer, when they swarmed, papa put mosquito-bar over his hat. They settled in the peavines and on the ground. I like to see bees swarm, especially when they are flying in the air. ORION HUNT.

Dodson, Ohio, Nov. 16, 1886.

You do not say how your papa recovered from the stings; but I gather from your letter that he did nothing, and just let old Dame Nature take care of it itself. Am I right? It is not wise to bump a swarm off from a limb when somebody is right below them, as I infer your father was.

HUNTING BEE-TREES.

Mr. Mase makes his home with my pa. He takes GLEANINGS. I read it some, and love to hear my pa and Mr. Mase read it. One year ago last month they found seven trees in the woods, with bees in them. They made hives and put them in. When it was cold they put them in boxes and put chaff around them. They all lived, and this summer the bees made 386 lbs. of comb honey in little boxes. I help all I can. I like to use the smoker. They took three more trees up this fall, and now have 16 hives of bees. I am 7 years old. I am too young to walk 2½ miles to school, so my ma and pa teach me and my little brother at home. CORA A. BLANCHARD.

Mt. Hope, Morris Co., N. J., Nov. 2, 1886.

FRED'S COLT, AND HOW HE TRAINED HIM.

I will tell you about a horse we had, and what Fred did with him. When the colt was about one year old, Fred thought he would try to see if he could not train him a little; so he commenced by leading him up to a log, and telling him to come up on it. Fred put one foot upon it for him, and then told him to put the other one up, helping him a little. Ever since that, when he wants him to come up, all he has to do is to say, “Prince, come up,” and he will come right up. He is very pretty, dappled light and dark gray. His mother is white as snow. She is very active when hitched to a wagon. Her mane is about 3 ft. 8 inches long. Her tail comes to the ground. Her foretop comes below the end of her nose. PEARL J. CRANSTON.

Woodstock, Champaign Co., O., Nov. 12, 1886.

I almost envy friend Fred, because I have not such a nice colt. The colt's mother, too, must indeed be a beauty, with such a long silvery tail and mane.

THIEVES, AND AN OLD KETTLE.

For the last year or two the thieves have been taking grandpa's chickens; and this summer, while they were trying to raise some little chickens, as soon as they were large enough for a good fry or roast, somebody would come and take them, and have a picnic, I suppose. There is a cornfield just below his cornfield; and when the corn-cutters came to cut the corn in the field adjoining his, they (we suppose it was they) commenced on his chickens, and one night they took an old kettle that grandmother's mother gave to grandmother when she went to Iowa. Grandfather thinks it must be over one hundred years old. This is pretty old, is it not? It was a kettle that was used to cook around the fireplace. He still keeps up with the old-fashioned cooking by the fireplace. The kettle was sitting by the side of the door where they keep all of the ironware. Grandfather was 88 years old in September, and I suppose the thieves think they can do any thing they want to around here.

PERL J. CRANSTON.

Woodstock, Ohio, Nov. 21, 1886.

If I were your grandfather, I think I would try to find out who those thieves were. That old iron kettle, by this time, surely has an unwritten history.

A GOOD SCHEME.

When my pa lived out west he kept a great many bees. He would buy common black bees and transfer them into frame hives, and Italianize them, and sell them for $10.00 a colony. We are going to Tennessee in the spring, and I am going to try pa's plan. I think every little boy can make money this way. I am going to study bee culture this winter, so I shall know how to commence my business in the spring. CHARLEY F. HENRY, age 12.

Lowell, O., Nov. 25, 1886.

Good, friend Charley! When you have transferred your first one or two colonies from “old gums” into the movable-frame hive, write and tell us about it, and we will send you any 25-cent present you may choose from our premium list or price list. You must remind us of our promise, at the time of writing. We will extend this offer to any other Charley who will do the same. Go among your box-hive men, explain the new methods of securing honey, and then offer to do the job of transferring at a price you and your box-hive friend may agree upon.

OUR HOMES.

Render unto Cesar the things that are Cesar's, and unto God the things that are God's.—MATT. 22: 21.

MY mind has been of late running quite a little on this thought of getting acquainted with people; of getting acquainted with our domestic animals; of getting acquainted with vegetation and the vegetable world, and especially with plants that furnish our daily food and our luxuries. You know how much happiness I have found in getting acquainted with the strawberry, and in learning its queer and wonderful ways of propagation and growth; and since then I have told you about getting acquainted with lettuce, celery, etc. I have also spoken about getting acquainted with the small boys who oftentimes annoy us. I have recommended a regular attendance at our county and State fairs, for the reason that we may, by this means, get acquainted with people, with their work, and with their industries. I have, at different times, recommended attending bee-conventions, because of the wonderful opportunity it gives us of getting acquainted with our brother bee-keepers.

Just as we were leaving the hotel at Ypsilanti for home, friend Hutchinson came up and said, in a low tone, that he had something to say to me, just as he shook hands to bid me good-by. What do you think it was? The remark was made for my private ear; but I am sure he will excuse me for giving it to your private ear, as it came to mine. It was, in substance, this:

"Mr. Root, I have noticed that, whenever I attend a bee-keepers' convention, I go away thinking better of some one than I did when I came."

It seemed a little odd just then, to be obliged to confess that he had expressed my feelings exactly. I felt a warmer friendship and broader charity, and a real honest respect and admiration for quite a good many of the friends who were there, that I did not possess when I started on my trip to Michigan. At the same time, I felt more conscious of my own faults and shortcomings. Now, if nothing else was accomplished than just these two results I have mentioned before, can any candid man or woman come to any other conclusion than that bee-keepers' conventions are an excellent institution, and ought to be encouraged? Any thing that tends to make us love our neighbors more and ourselves less, strikes toward godliness, and strikes heavenward, does it not? Any thing that takes the conceit out of our own hearts, and helps us to "see ourselves as others see us," raises us up, does it not?

One of the best topics for discussion that came up was the matter of ripening honey. Shall we allow the bees to ripen it in the hives, or shall we throw it out of the combs before it is capped over, thus saving labor in two ways? First, because it flies out of the combs with so much less power applied to the crank of the extractor; snd, secondly, because all of the slow, dauby work of uncapping is saved. Of course, there were different opinions. Prof. Cook and good friend Muth have for years declared there was no need of waiting for the honey to be capped over; that it would ripen in crocks or large tin cans, with a cloth tied over the top, just as well as it would in the hive. Friend Cook is about as good authority on most subjects as you can find in the State of Michigan, or any other State; that is, such is my opinion. Friend Muth has handled more liquid honey than perhaps any other man in the world; and he has a reputation for handling only a good article, almost (if not quite) second to none. Notwithstanding this, I once almost ruined our honey-market by extracting honey when it was too thin, and bottling it up and putting it on the market in that shape. Friends Cook and Muth say that I ought to have left it in an open vessel until it got thick and thoroughly ripened. Friend Cook stated that his brother had, during this past season, secured 16,000 lbs. of honey by throwing it out before the combs were capped, and then evaporating it in sap-pans placed in his granary. This granary is in a very warm place, exposed to the sun's rays. To keep out the dust, the pans were covered with coarse cotton cloth. Prof. Cook pronounced the crop equal to any honey he had ever seen, and called upon Mr. John Rey, who was present, to state how it has passed among the people; for Mr. Rey had purchased the entire crop. Mr. Rey rose and stated that it pleased everywhere, and that it was the best honey he ever handled. At my suggestion a bottle of it was passed around, and I called it almost if not quite equal to our very best honey from white clover. Friend Bingham and others, however, took the opposite side of the question; and when friend B. submitted to me a jar of honey that was ripened in the hive, and bottled up as soon as extracted, I was forced to admit that it had a richness of flavor that the other honey did not. One reason, however, that the latter sample was more agreeable to my taste, was, that it had just a trace of basswood—just enough to spice it a little. Friend Bingham, as I thought, bore down on friends Cook and Muth a little too hard, and he vehemently objected to having their report published in the journals—especially in Gleanings. The point he made was this: That in many places we have, most of us, almost ruined the demand for liquid honey; but we have since pretty nearly recovered it by being very careful to furnish none but an excellent quality of nice honey, thoroughly ripened on the hives by the bees, and that, if we attempt to put off on our customers honey ripened by artificial means, we shall get into trouble again, and may be never get out of it. Novices in bee culture, and greedy, selfish men generally, will neglect to ripen the honey as thoroughly as they *might do* by artificial means, and thus do us no end of damage.

Just now an incident occurs to me that I did not mention then, but I want to mention it now: Some four or five years ago I undertook to assist the farmers in our vicinity, by taking their crop of maple syrup off their hands. I decided to buy nothing but a first-class article, and have it immediately soldered up in tin cans, so it would reach my customers with the fine aroma it possesses when properly put up. Almost immediately people urged and argued to have me purchase syrup that my better judgment decided was *too thin*. One good man, who is a professor of religion, and who stands pretty fairly in community, urged and argued so keenly that his syrup was thick enough to keep well, that I bought it. He said, that, if made any thicker, it would candy in the cans—it could not be got out, and that it was really a superior article. One of my weaknesses from childhood is, that I am easily prevailed upon, especially if I stop to talk and listen. Some of the friends may, at different times, have felt very hard because, of late, I decline long discussions. Well, one reason is, that I have found it better for all parties concerned to say *no* at the outset, even if I do make some enemies by it, than to allow myself to be persuaded contrary to my better judgment. I bought the syrup, canned it up that very same day, and it was mixed in with perhaps 200 or 300 cans. About every customer who got a can of this syrup was mad. Sometimes one would write to me, remonstrating; at other times they would say nothing. They probably bought their maple syrup and other things somewhere else next time. There has been a good deal of talk and legislation about the adulteration of syrups. I am inclined to think the maple-syrup business has been injured more by shortsighted and stingy farmers (the word "stingy" sounds a little harsh and slangy, but it seems to me it just about hits the mark) than by all the adulteration we have ever had. Good thick well-ripened syrup, like good well-ripened honey, is good when it is put up, and it is good for ten years after, or more. In fact, it is *always* good. But you don't get nearly as many gallons when you ripen it down real thick. I have mentioned this latter matter to show you that friend Bingham had a good point, and there was some reason for his bearing on hard. I have been told by those who had visited friend Bingham at his home, that he is very careful and nice about every thing he does. He believes in furnishing the best that can be produced; and when he purchases he likes to get such as he himself gives. I believe he is a jeweler by trade, and probably on this account has learned to be neat and nice about all his work, furnishing good work and getting good pay for whatever he has any thing to do with. I hope friend Bingham will excuse me for the above, but he has been somewhat criticised for what people call his odd ways, and I confess that I have myself felt tried with him, because he sticks so strongly to what I have been in the habit of calling his own notions. I felt like criticising him at that time; but I want to tell you what made me reverse my opinion very quickly. It was to see him, with such perfect self-command and pleasant good nature, drop the whole subject and pleasantly take hold of something else when he had had his "say."

Did it ever occur to you, friends, how often a hearty good laugh will wake everybody up, drown all sorts of wrong feelings that may have arisen, and restore perfect equilibrium? Well, something of the kind came in right here. It was a simple, trivial matter, but it was almost dinner time, and a good many of us had been sitting still longer than usual. We were just ripe for some thing funny, and we were ready to hurt ourselves laughing, even if it were not so very funny, after all. Did you ever see a lot of school boys and girls in just that frame of mind? Well, friend Bingham, in describing the virtues of good old honey, perfectly ripened by the bees themselves, used ripe old wine and other intoxicating liquors as examples. He dilated to such an extent on the rare virtues of a bottle of wine that for years had been kept cork downward, covered with cobwebs, and some other similar illustrations, that Prof. Cook finally called him to order, and desired him to stop using illustrations that might awaken in some of us feelings that were better allowed to slumber. The above are not the words used, but the substance. Now, when the president (Prof. Cook) got up to reply, he took up a little glass pail of honey for an illustration. Friend Cook does not often get much excited, but he was full of enthusiasm in defending his side of the question. The people of Ypsilanti had given us a very pleasant hall for our meetings. The speaker's desk was on a raised platform, one step higher than the rest of the floor. Now, the desk and chair for the president were raised still another step; and as it was well carpeted, one might forget these different steps, if he didn't take care. The president, in order to make his point plainer, attempted to step out from his desk, to get nearer his hearers. In doing so he forgot the step, and went headlong right on to the secretary, with his pail of honey. The secretary made a dodge and looked up in astonishment. Friend Cook, in regaining his equilibrium, made some more stumbles, but, of course, out of respect to our beloved president's feelings, we all of us tried to keep our faces straight. At this point friend Bingham arose, and, with great dignity, and in his inimitably dry way, borrowed a part of the president's very words, something as follows:

"Mr. President, I earnestly protest against such illustrations here before this respectable audience—illustrations that might suggest," etc.

Those who had tried to keep back the smiles a moment ago, apparently decided it was no use to try any longer, especially to think of the idea, so utterly ridiculous, as to suppose for an instant that our earnest temperance friend behind the desk could by any possibility have taken any thing that might interfere with his remarkably clear head and steady bearing. I laughed, and laughed again, every time I thought of it, until I was really afraid I should hurt myself.

Now, this good-natured pleasantry is a simple thing, yet it had much to do with the general good feeling of the meeting. There seems to be, if I have made no mistake, a general air of gentleness and good breeding among all the Michigan friends; in fact, it seems as if it were a recent growth; for over and over again, when there seemed to be a little danger that somebody's feelings would be hurt, stout and kind hearts at once rushed to the rescue, and I am sure that no one went home feeling in the least bit hurt by any thing that was said or done during the two days' deliberations. I have been in the habit of saying that it was very hard work for me to sit still during an ordinary lecture; but there I sat from morning till night, again during the evening, and again the *next day* from morning till night, and I felt sorry when the convention was over. Perhaps one reason why I enjoyed it, was because they very kindly allowed me to get up and talk myself, every little while. And now, friends, with the above preface before us I am prepared to take up the little text that appears at the head of my talk to-day.

Some time ago, friend Abbott (originator and former editor of the *British Bee Journal*) mailed me a sample of a new honey-knife he had just got out. He said they were made of the best Sheffield steel, but that, by ordering large quantities, just as we do here in the United States, he could get them at a price that would enable him to lay them down here in America so we could furnish them to the bee-friends here at a very much lower price than any thing else on our markets. As friend Abbott has paid us thousands of dollars already for bee-supplies, we felt somewhat in duty bound to trade with him when he offered something we could use. England excels the world in cutlery, I believe; and with her resources and cheap labor many things can be furnished cheaper than we can possibly get them up here. I did not, however, at once give him the order—not because the knife was not a beautiful one for the money, but because it is a copy of the Bingham & Hetherington knife, with the exception of the uncapping part of it. Now, friend Abbott has not infringed on anybody's patent, because the knife is not patented in England. I am not well enough versed in law to say whether I should be infringing or not in bringing these knives into the United States; and there is no infringing at all any anywhere, unless the patent belonging to friends B. & H. covered the plain knife without any cap-catcher. A copy of their patent-claim, procured later on, showed the patent was on the cap-catcher and on nothing else.

It did strike me at the time that it would be an act of courtesy to forbear bringing in an imported knife, evidently copied from an American knife. On the other hand, should the bee-friends in America be asked to pay a dollar for a knife which could easily be sold for two-thirds or less by getting it made in England? In such cases it is customary to say we should choose the greatest good to the greatest number. Something called my attention to other matters, and, without thinking much about it, an order was sent to friend Abbott for thirty dozen knives. The knives were advertised in our last issue. Now then: A part of my readers will doubtless take sides with me, and say that I did nothing out of the way. Another party will perhaps be surprised to hear a man like myself, who teaches morals to the people, publicly confess to having yielded to such a temptation. I think I shall join with the latter class. I am ashamed that I allowed my better judgment to be set aside in the matter, and I publicly beg pardon of friends B. and H., and promise that not a knife shall be sent out (for not one has yet been sent out in answer to the advertisement). If I can not arrange with friends B. & H. to pay a royalty for the privilege of selling a copy of their knife, or something in that line that shall have their sanction, the knives shall remain on my hands. The above course of action is very plainly the only proper one, according to the code of moral law laid down by my very self not very long ago; and even though it hits me a terrible clip right here, I think it will be well to give it again:

A. I. Root in regard to copying other people's inventions or ideas. Written Sept., 1884.

> I am very glad to note the disposition among bee-keepers, of forbearing to copy the works of each other, patent or no patent. The supply-dealer who would unhesitatingly copy something well known to be the property of another, without getting the privilege of so doing, by purchase or otherwise, would very likely lose more than he made, so strong is the disposition of our people to give honor to whom honor is due.

In the light of the above, it is not our business to inquire what features the patent covers, or, in fact, to inquire if there be a patent at all. If any of the bee-friends have introduced something to the people that no one had seen or thought of before, we should, out of courtesy, forbear to copy it, no matter how simple it may be. Honey-knives, very much like those made by friends B. & H., were sold before on the market, except that they were not ground all on one side like a chisel. Very likely the Patent-Office would not grant a patent on making any cutting tool with the above-shaped edge. But friend Bingham had a particular idea in view when he made his knife of a thick piece of steel, and ground it in this manner; besides, he has for years had undisturbed possession of the idea. Nobody has even claimed to have used the principle before, that I know of. Now, the fact that I give all my inventions to the world, and have no patents, has nothing to do with the question. I publish a journal purposely to teach, and I try hard to make the journal valuable, so that it may have a large list of subscribers. I get my pay by receiving a dollar from each of you, instead of getting it by controlling a patent. Friend Bingham does not publish a journal. He has his own methods of disposing of what belongs to him, just as I have my method. You may think it strange, when I say I did not think of having done any thing wrong until I met friend Bingham at the convention, and got acquainted with him. I did not say any thing to him about the honey-knife, because I had not considered the matter sufficiently to be able to decide what to do. As I view it, I have done wrong, and thirty dozen honey-knives shall not stand in the way one single moment. I am satisfied of what I ought to do.

Why do I make this matter public, when it might be settled in private? First, because the knives are already advertised in our journal and price list; second, because there has been hard feelings and troubles in this very matter before; and when I have publicly forgotton to follow my own teachings, I wish, just as publicly, to set an example in the way of owning up and making restitution. I wish, too, to "render unto Cesar the things that are Cesar's, and unto God the things that are God's." Attending the convention I have been telling you about has had very much to do in coming to this decision, and I think there is very much less danger of doing people injustice and wrong when we get well acquainted with them than where we do not know them, especially where they are off at a great distance. If this is true, let us get intimately acquainted. Let us attend not only conventions, but farmers' institutes, the State and county fairs, public meetings, lectures, etc.; and as the present age offers facilities that the children of men never enjoyed before, for a free and full interchange of knowledge and ideas, is it not possible that the glad millennium is coming a great deal in this way? May it not be true, that our facilities for travel, and the abundance of books and periodicals on almost every subject, are working toward the time when God's kingdom shall come, and his will be done on earth as it is done in heaven? and may it not be that the next step to be taken by us as individuals, as states, and as nations, is, in the language of our opening text, to "render unto Cesar the things that are Cesar's, and unto God the things that are God's"? May God help us to make any needed sacrifice to this end!

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

CONVENIENCES FOR THE APIARY, CONTINUED.

OUR readers are well aware that we have a large queen-trade from year to year. As we have found that from three to four hundred colonies were inadequate to supply the demand, we have been compelled to order from the South, especially in early spring. At times the influx of queens from this source exceeds the demand; and rather than let the queens lie idle—possibly die—we put them into the apiary, to do service. As might be imagined, then, our experience in

INTRODUCING QUEENS

Has been quite extensive. We can not, therefore, employ any means to this end which is not almost absolutely sure. We use exclusively the Peet process, or an introducing-cage based upon this principle of automatically releasing the queen. If, therefore, I tread a little over old ground, I do so with the intention of gathering up a few details which have never been fully described or illustrated. I shall, then, show exactly the manner of introducing with the Peet cage, together with the position of the operator. In no better way can I do this than by presenting you a picture of the modus operandi exactly as it occurred in process in our own apiary.

The cut, as you will observe, is a view up one of the avenues of our apiary, with the grapevines on either side, looking from the southwest. In the foreground is posed your humble servant, not in his Sunday go-to-meetin' clothes, but attired in his apiary garb just as you would see him when at work among the bees were you to visit our apiary. That every thing might appear easy and natural, our artist has taken the view as seen on next page. Before passing on I will ask my reader to note carefully the straw cuffs about the wrists, and the cloth broad-brim hat, as I shall, in next issue, have occasion to write an article on "dress for the apiary." With this slight digression let us hasten on.

We will presuppose that the queen, or queens to be introduced, are at hand; that we are rigged out *cap a pie*, with our bee-suit, the smoker lighted, and the hive opened as above. We will then revolve the tin points at right angles to the tin slide, not forgetting to see that the latter will slip off easily. If, from expansion of the wood, the slide should stick, with the point of a knife bend out the folds in the tin until it will slip off easily. If we do not take this precaution, after the cage has been fastened upon the combs, in case the slide should stick, the latter is liable to come out with a jerk, which may release the queen, or anger the bees. Having seen that every thing is all right we remove one of the frames and stand it leaning against the hive in such a way as not to crush a single bee, as shown in the engraving. With smoker in hand, and a few spears of grass (long timothy preferred), brush a clean place on the comb* clear of bees, using the smoker just enough to assist. This done, and the tin points revolved as before described, we proceed to push them through the combs in the manner shown. Although I do not always strike the attitude as shown, yet from convenience it is the one I usually assume when fastening the cage to the comb. While pushing the points in, it is altogether likely that a bee or two will run under when you would particularly desire him not to. A little puff of smoke will usually drive them out, then quickly push down.

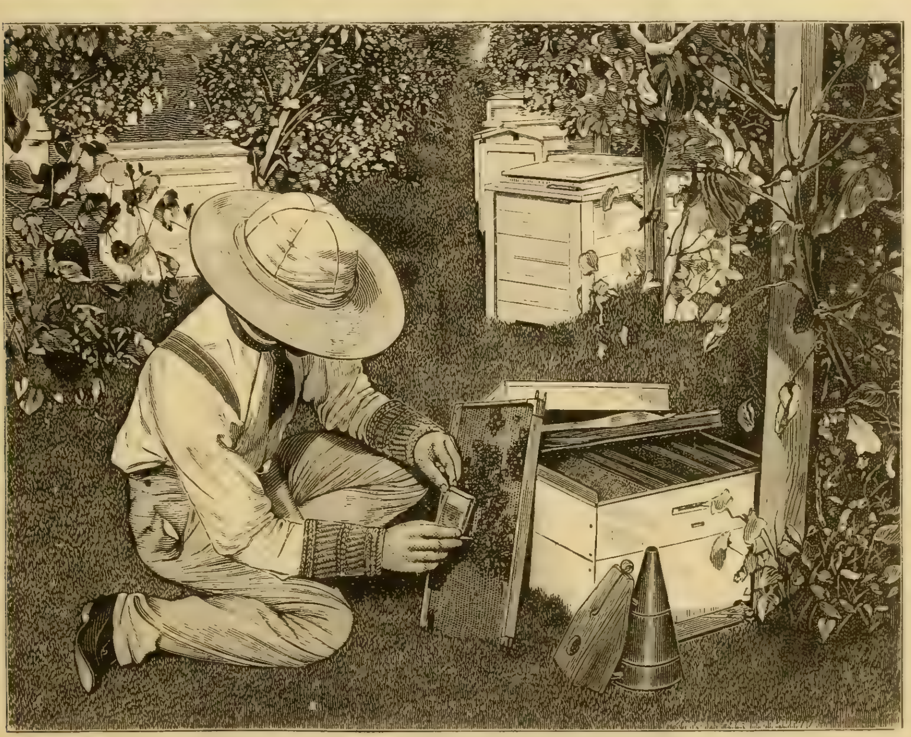
We will now carefully draw out the slide by catching the folded edge with the thumb-nail or the point of a pen-knife. Last of all we bend the points backward on the other side of the comb to clinch up securely. If we clinch the cage on the comb first, and then draw the slide, in all likelihood the operation will loosen the cage; hence we always first draw the slide and then clinch the tin points.

This is a small matter, I know; but it is just some of these little details that are often the essential elements of success. The comb, with the cage attached, we must carefully place in the hive, having previously spaced out the combs to receive it. We now space up the combs, but allow a little more room for the frame to which is fastened the cage. The little slate, or tablet, on the hive is marked, "Imp., cgd 21st," which means, in full, that on the 21st of the month we caged an imported queen in that hive. If the queen is an untested one, thus: "$1.00, cgd 25th;" if tested, "Test., cgd 29th;" if select tested, "$3.00, test., cgd 8th." The hive, as thus marked, is left for two or three days, at the expiration of which time, in the great majority of cases, the queen is automatically released without any trouble on our part. Besides this, the queen may be laying in addition. When we discover that the queen is out, and all safe, we remove the cage and mark the slate, "Imp., out 24th."

---

*I omitted to mention right here that the spot of comb selected should be old and with an even surface. The patch should also contain some cells of unsealed honey.

Without overstating, I do not think we lose one out of every fifty queens so introduced. Neighbor H., who has also had a large experience with the Peet cage, says that he can not remember that he *ever* lost a queen by the Peet process. Not only this, it has been our practice, after taking out one queen, to cage another in her place, with results as above recorded. Beginners and others, unaccustomed to the plan, will not obtain such results; but I have thus gone into details that all might profit by our experience. The whole secret of the Peet process, I think, rests in the fact that the queen can be or should be so caged as to have access to a few cells of unsealed honey, and that the bees release her *themselves*. The act of opening a hive, and disturbing its normal condition, is liable to cause the bees to ball the queen if she be released by the apiarist, which is necessary by the old methods; hence I would not encourage the beginner to release the queen in a Peet cage if she is not already liberated in two or three days by the bees, *providing* that she and her attendants still have access to a few cells of honey, and that she apparently is in good condition.



THE PEET PROCESS OF INTRODUCING QUEENS, SHOWING THE MANNER OF FASTENING THE CAGE UPON THE COMBS.

COMB-HOLDERS.

Perhaps some one may inquire why, with all our facilities, we do not hang the frame in a comb-holder, and then fasten on the cage. It is too much trouble to lug the comb-holder about; and aside from this, we can not afford the time to stop and fuss, just to hang the frame as it is in the hive. I very much prefer to lean a comb, with or without adhering bees, against the hive, as seen in the engraving. During hot sunny days, however, I am careful to lean the frame on the shady side of the hive. I can then at leisure catch and cage a queen for shipment, or introduce one.

THE KLIMITZ QUEEN-CATCHER AND INTRODUCING-CAGE.

The principle of the Klimitz cage (automatically releasing queens) is similar to that of the Peet; but instead of eating away the comb as in the Peet to gain access to the queen, the bees eat out a plug of candy.

Having put a queen in several of these Klimitz cages, I laid them directly upon the cluster of queenless colonies. The bees, in a couple of days, ate out the candy and liberated the queens, all of which were successfully introduced.

GLEANINGS IN BEE CULTURE.

Thou shalt not covet . . . . any thing that is thy neighbor's.—EXODUS 20:17.

HONEY RETAILED FROM FULL-SIZED L. FRAMES.

IN regard to the price received, as per page 946, last issue, friend Fradenburg replies as below:

> Referring to your foot-note on page 946, I will say that our grocer here has sold my comb honey from the L. frames at 15 cts. per lb., and sections at 18 cts., and I allowed him 15 per cent for selling. That which I took to Uhrichsville netted me 13 cts., but I believe they sold the most of it at 20 cts., so you see it is not such awful cheap honey after all, is it?
>
> Port Washington, O., Dec. 9, 1886. A. A. FRADENBURG.

THE FARM JOURNAL, OF PHILADELPHIA.

WE presume most of our friends are already acquainted with this original, crisp, go-ahead little sheet, at the low price of 50 cts. a year. If not, they had better drop a postal for a sample copy. And, by the way, we must not forget to mention that it was through the kindness of said journal that we are able to present the excellent picture of friend Terry, on page 975. The portrait first appeared in their pages, and they were kind enough to let us have an electrotype.

STATE BEE-KEEPERS' CONVENTIONS.

IF there is to be a bee-keepers' convention at Columbus, O., will some of the friends please tell us when and where, that it may be generally understood in time so we can endeavor to call out a good attendance? I confess I have been very backward in these matters; and I even omitted to mention beforehand that I expected to be present at the State Convention in Michigan. Through God's providence I am feeling unusually strong and well, and I propose to be present at the N. Y. State Association, at Albany, Jan. 11, 12, 13, 1887. If my presence can be the means of bringing the bee-friends together, and helping them to get better acquainted with each other, I mean to try to be on hand, whether I "feel like it" or not.

A DISTINGUISHED VISITOR.

WE have been enjoying a very pleasant visit of several days from Mr. James A. Abbott, son of C. N. Abbott, the originator and former editor of the *British Bee Journal*. Mr. Abbott brings with him a tin can for extracted honey, that beats the world. It can be opened and closed in an instant, and yet it is absolutely honey-tight. The different sizes nest together like our honey-pails. He also has taken our order for a honey-label in six or seven different colors, that is neater and more unique than any thing America has ever produced, so far as I know, and yet the price is so moderate we hope to be able to sell them at a price not to exceed $1.75 per 1000. The label is small. Small labels are getting to be more in vogue, especially for glass receptacles. If it were a possible thing, I tell you I would give a good round sum of money to have the readers of GLEANINGS *en masse* listen to a piece of music executed by Blue Eyes and our young friend Abbott—Blue Eyes having a piano, and Mr. Abbott a silver flute which he brought from England.

SPECIAL NOTICES.

A CARPET-SWEEPER FOR A CHRISTMAS PRESENT FOR YOUR WIFE.

I DO not know who in the world deserves a Christmas present more than the "queen of your household," as Prof. Cook puts it. And if she is in the habit of sweeping (and what household queen is not, more or less?) I do not knew of a nicer and more appropriate present than a carpet-sweeper. Price $1 50; extra decoration, and finished expressly for the holiday trade, $2.00. This latter one has a rubber band clear around the machine, so the juveniles can not bump the furniture and mar it, when they take a notion to help mamma do the sweeping.

MAPLE SYRUP FOR THE HOLIDAYS.

WE to-day bought of one of our Medina Co. farmers 88 one-gallon jugs full of maple syrup. Each jug has his name and guarantee labeled on the outside. Although it is not as light in color as some we have seen, it is quite thick, and the flavor we consider very good. It is the real old-fashioned maple molasses, such as your mother used to give you when you were a schoolboy. We can furnish it in its original shape, jug and all, for an even dollar, or we will put it in a syrup-can at the same price, if you prefer to have it shipped in that way. If you want as much as four or five gallons you had better have it in one of our shipping-cans for extracted honey. It will cost you just the same in this shape, but there will be a saving in freight.

PROF. COOK'S BOOK ON MAPLE-SUGAR MAKING.

And this reminds me that the manuscript for a little book on maple-sugar making, is now in the hands of our printers, and the author is no other than Prof. Cook himself. The book is to be profusely illustrated, and will no doubt prove a boon to thousands. Prof. Cook has a model sugar-bush of his own, and I do not think there is a single modern improvement in this wonderfully fascinating industry that he is not perfectly familiar with. The book tells how deep to bore the holes, and the reasons for it. He tells how many holes to put in a tree, the advantages and disadvantages of having the holes high up or low down. He also gives the fullest particulars in regard to producing gilt-edge maple sugar and maple syrup, with the reasons fully explained for every thing he directs. In size it will probably be about the same as Terry's potato-book, and the price will be the same; namely, 35 cents; 40 cents by mail, postpaid. If you want a copy of the book just as soon as it is out, send in your 40 cents when you are making remittances.

CONVENTION NOTICES.

The next meeting of the Sheboygan Co., Wis. Bee-Keepers' Society, will be held at Hingham, Jan. 13, 1887. MRS. H. HILLS.

The bee-keepers of the western part of Ontario, Canada, will hold a convention at Tilbury Center, Jan. 12 and 13, 1887. All are invited to attend. N. SMITH, Sec.

The Northeastern Ohio, Northern Pennsylvania, and Western New York Bee-Keepers' Association will hold its eighth annual convention in Chapman's Opera House, Andover, Ohio, on Wednesday and Thursday, January 19th and 20th, 1887. First-class hotel accommodations at $1.00 per day to those attending the convention. A general invitation is extended to all.

M. E. MASON, Andover, O., Acting Sec.
C. H. COON, New Lyme, O., Pres.

The eighteenth annual convention of the New York State Bee Keepers' Association (formerly Northeastern) will be held in Agricultural Hall, Albany, N. Y., on the 11th, 12th, and 13th of Jan., 1887. The first session will open promptly at 2 o'clock P. M. of the 11th. The Eastern New York and the New Jersey and Eastern Associations will also unite with us, thereby assuring this to be the largest, most interesting, and instructive convention ever held. No bee-keeper living within 500 miles of Albany can afford to stay at home. Questions of great importance will be discussed by many of the most noted and experienced bee-keepers in America. A grand exhibit of honey and apiarian fixtures is also promised. All implements for the apiary, sent to the Secretary, will be properly arranged for exhibition. Full programme will appear in next issue.

W. E. CLARK, Pres. G. H. KNICKERBOCKER, Sec.

INDEX TO ILLUSTRATIONS.

Anterior Leg of Worker 669
Apiary Belonging to J. B. Haines 295
Apparatus, Sproule's, for Disinfecting Foul Brood 460
Arrangement for Holding 1-lb. Sections on the Hive 455
Arrangement, Gould's, for Combining a Section-case and Separator 858
Ash-sifter, Rival 61
Barn and Tool-house, T. B. Terry's 396
Bee-tent, Folding, Ready for Use 950
Bench-vise, Our 15 cent 402
Box for Raising Plants 60
Box, Rawson's, for Starting Squashes, etc 738
Can for Saving Ashes 216
Cary, Wm. W 11
Celery-plants, A Box of White-Plume 217, 492
Chaff Hive, the C. P. Bish, Showing the Simplicity Body Filled with Sections 128
Climbing Belleflower 767
Cold-Frames 139
Colony of Bees Living and Prospering Without a Hive 608
Comb, Apis-Dorsata 124
Corks, Putting into Bottles, Device for 265
Drone-Bee 146
Drone-trap, The Alley 461
Eye of a Bee 42
Fairground Exhibits 816, 929
Faucet, Poultry 314
Feeder, D. A. Jones's, and Feeding the Good Candy 53
Feeder, Bread-pan 914
Feeder, Simplicity 914
Foul Brood, Apparatus for 460
Frame, The Simplicity Reversible 550
Frame, Kretchmer's Reversible 980
Fumigator, Webster's 756
Greenhouses and Hot-beds, W. W. Rawson's, Arlington, Mass 739
Greenhouses, Henderson's New Method of Building 140
Greenhouse, Our 142
Greenhouse, Our Preference 141
Harrow, Acme, with Sulky Attachment 407
Harrow, The Thomas, as Used for Cultivating Potatoes 498
Heddon, James, Dowagiac, Mich 440
Hen's-nest, Movable 314
Hive Composed of Narrow, Shallow Brood-Chambers 205
Hoe, Double-Wheel, the "Planet Jr." Earthing up 497
Honey-Board, Queen-Excluding 618
Honey-Can, Our New 58-pound 274
Honey Exhibit, E. R. Newcomb's 929
Honey-Knife, Ten-cent 126
Honey-Plant, Chapman 673
Hook, Gimlet-Pointed 7
Human Eye, Section of 43
Introducing by Peet Process, Illustrated 1001
Introducing-cage, Peet's 459
Johnny's Dream 318
Kite, Our Ten-cent, for the Juveniles 850
Kohlrabi 578
Leg of Worker, Anterior 609
Lettuce, Boston-Market, When it is just ready to Cut 575
Lettuce, Peter Henderson's New "New York." 579

THE CHAPMAN HONEY-PLANT.

Having expended thousands of dollars in bringing before the people one of the most wonderful honey-producing plants known in the United States, or even in the world, and testing it honestly and fairly, I wish to say, through GLEANINGS, that the seed contains so much oil that nothing but fresh seed will grow for this reason; and by the advice of many prominent bee-keepers I have decided to sell the limited amount of seed I have raised this season, at the following prices. I will send to those who have already ordered the amount of seed due them at this low price: ½ ounce, 50 cts.; 1 ounce, $1.00; 2 ounces, $1.50; 4 ounces, $2.00; 8 ounces, $3.00; 1 pound, $5.00. One ounce contains from 1600 to 1800 seeds. The seed should be sown in early spring, and general directions for cultivation will be given on each package. Write all orders plainly, and give your postoffice in full.

H. CHAPMAN,
Versailles, Cattaraugus Co., N. Y.

P. S. See official report of the committee in next issue of GLEANINGS.
